C The reason of this I have ascertained to be as follows:

On the ordinary systems of welding it is the practice at once to lead a current to the objects to be welded (such as iron bars, hoops, chain links, or the like) whereby, in consequence of the thinner or thicker layer of air, which is always present between the two objects, vigorous sparking occurs. There is, so to say, a line of sparks or an arc formed, which persists until the objects being welded have been brought to welding heat by the electric current, whereupon they are finally pressed together to effect the desired union.

This well-known method, therefore, does not really differ from the ordinary method of welding at the fire, except that instead of the gases of combustion of the fuel, the electric current is employed to heat the bodies to be welded. Once the welding heat is reached, however, the final union of the bodies in either case is effected by mechanical pressure (pressing or hammering).

Amendment Filed with letter Jul. 9/04.

For the purpose of enabling my invention to be more readily understood, I will make reference to the accompanying drawing, in which

Fig. 1 is a sectional view illustrating the electric welding of two comparatively thick sheets on the ordinary system.

Fig. 2 is a like view showing what occurs when one of the sheets is thin.

B. Fig. 3 is a section of portions of two thin sheets with an air-gap between them.

Fig. 4 is a sectional view illustrating the employment of my new process in welding thin sheets.

Fig. 5 is a like view showing the welding of the overlapping ends of two pieces of sheet metal.

As Fig. 1 shows, the electrodes *a b* lie opposite each other, the sheets *1*, *2* to be welded by the ordinary process being located between them. The sheets lie loosely upon each other, that is to, say they are not artificially pressed together, and the consequence is that they are separated by a layer of air 3.

If now the electric circuit is completed through the two electrodes and the sheets, and if the layer of air *3* is sufficiently thick, that is to say, the air resistance sufficiently great, there will be no sparks or arc formed between the two plates for the time being. If, however, the sheets are approached, as is unavoidable for the purpose of final union by pressing, hammering, etc., as already explained, a time must arrive when the air resistance between the two sheets to be welded is no longer sufficiently great to prevent equalization of the electricity at the two poles. Between the sheets, therefore, an arc or a line of sparks will be formed, and will continue until intimate contact has taken place between the two sheets. If, as is shown in Fig. 1, the sheets are relatively thick, the arc which is formed will be of no consequence, since the slight fusing away at *4* caused by the arc, or the sparks, will not be sufficiently deep to penetrate the thick material. In fact, there is even an advantage in the action of the sparks or arc in the case in question, since the cross section of the material is altered, whereby the two sheets are, as it were, scarfed at the place of welding, that is

B. to say, the two cross sections are diminished at the seam to approximately the thickness of a single sheet, so that under certain conditions the two welded sheets have the same thickness at the joint as a single sheet.

The case is altogether other when two thin sheets or articles are to be welded, or when a very thin object is to be welded to a thicker one, such as is shown, for instance, in Fig. 2. In this figure it is assumed that the thick sheet 2 (which, as explained with reference to Fig. 1 is thick enough not to be penetrated completely by the arc at the point 4) is to be electrically welded to a very thin plate 5 by the ordinary process as above explained.

On the approach of the objects *2*, *5*, at a certain moment, in consequence of the penetration of the layer of air *3*, fusing away takes

place at *4*, owing to the arcs or sparks, and this fusing will extend to such depth that, although, as above explained, not injurious in the case of the sheet 2, it causes the thin sheet 5 to be completely perforated or burnt through. Thus the ordinary process of welding by means of an arc is quite impracticable with thin sheets as represented in Figs. 2-5.

C. The essential feature of my invention is that in welding thin sheets from about two millimeters in thickness downward the formation of such an arc, or sparking distance, which proves so disastrous, is wholly avoided, whereby a perfectly sound welded joint between such bodies, or between a very thin body and a thicker object, is attained.

B. For the purpose of preventing the formation of the injurious arc, that is to say, the sparking distance, I first submit the superposed metal objects to be welded *5*, *6* (Figs. 4 and 5) to a certain pressure, the amount of which will depend upon the nature of the said objects. This pressure I effect by means of the electrodes *a b* (Figs. 4 and 5) themselves, or with the aid of other suitable means. The purpose of this pressure is to bring into intimate contact the parts of the metal to be united, so that the layer of air between them is as far as possible expelled. In this manner the two parts to be welded are, as it were, mechanically connected to form a single homogeneous body. This is of great importance when the two very thin sheets are to be welded together. For, as is well known, thin sheets have always a more or less wavy form, so far as they have not been straightened in the process of manufacture, so as to present a surface which is practically quite flat, such as is the case with thick sheets. Such thin sheets, therefore, unless submitted to mechanical pressure never lie close upon one another; on the contrary, in consequence of the waved form, large air-gaps 3 (Fig. 3) are left between them, so that if a current were led through them, it would aid sparking and the formation of arcs.

After the two metal objects have, therefore, been prepared in this way, that is to say, by the application of mechanical pressure caused to lie closely upon each other, without any air-gap, between them, the electric circuit is closed, the mechanical pressure being still maintained.

B. At the place where the electrodes *a b* exert pressure, therefore (Figs. 4 and 5), that is to say, where the current is able to flow through the bodies to be welded without having to pass through a layer of air and form sparks, the metal is heated to welding heat. Immediately this temperature is reached, the continuous pressure effects the desired union, that is to say, welding of the two metal objects 5 and 6, without injury by perforation or burning, in the manner explained, having taken place, even if the sheets are extremely thin. It should be remarked that the pressure to be exercised on the bodies before and during welding, must be

selected according to the thickness of the sheets, and can be adapted to suit the condition of the bodies for the time being. Thicker sheets or objects do not require so much pressure as thin ones because, as already explained, they have a more even, uniform shape and therefore when laid upon each other can be readily closed together, that is to say, pressed so that no injurious air-gap is formed.

Since the essential condition is, that the two metal objects to be united are firmly pressed together before welding, in order that complete penetration of the thin body by the electric current may be avoided, it is obvious that with this process not only two equally thin sheets, but a very thin sheet and a thicker metal object may be welded without danger of the former being burnt through.

Naturally the required superficial pressure may be exerted by only one electrode, or by both the electrodes.

Having thus fully described my invention, what I claim as new, and desire to secure by Letters Patent, is:

The herein described process of electrically welding thin metallic sheets, which consists in applying electrodes on the metallic sheets at the point at which the joint is to be formed, then forcing the electrodes on the sheets sufficiently to press the same intimately together at the point at which they are to be welded, then heating the metallic sheets by passing an electric current through said electrodes and through the sheets, and maintaining the pressure of said electrodes on the sheets during the passage of the current through the electrodes and the sheets.

AMENDMENT.

In the Canadian Patent Office, Application of Johann Harmatta, Electric Welding, Serial No. 108,990, Filed December 1, 1903.

Defendant's Exhibit No. 52.

Hon. Commissioner of Patents,
Ottawa, Ont.

Sir:

We return herewith the duplicate specification and drawings amended. We also send you a second copy of the new specification with claims, and an extra copy of the new claims. We send also one drawing on cardboard of new figures 1 to 4 inclusive, and a copy on tracing cloth of these figures. We attach to the present letter a blue-print of the original drawings filed, where you will find A. that we have erased original figures 4 and 6 and re-numbered the other figures. The alterations to the original drawings are indicated in red on the blue-prints, and we hereby authorize and request the Patent Office to make similar corrections on the drawings retained.

It is hoped that the application as now amended will be found allowable, and an early issue of the patent is respectfully requested.

Respectfully submitted,

MARION & MARION,
Attorneys.

M./M.

To all whom it may Concern:

Be it known that I, Johann Harmatta, Engineer, a subject of the King of Hungary, residing at Szepesvaralja, in the Kingdom of Hungary, have invented new and useful "Improvements in Electric Welding," and I do hereby declare that the following is a full, clear and exact description of the same:

My invention relates to a process of and apparatus for manufacturing metal articles of all kinds, in particular those of the thinnest sheet metal, by direct electric welding. The new process consists in one of the electrodes (or both of them) not only serving to feed the current, but also being employed for exercising a more or less strong pressure either before and during the period of supplying the electric current, or only at the moment of this supply, at the place at which the welding is to be done. The member which feeds the electricity is thus at the same time the tool, and in this manner the most favorable conditions of working possible are secured, since, as is well known, in really effective welding processes the place of welding brought to the proper temperature must be at once well hammered or pressed in order that the welding may be thorough.

According to none of the present known electric welding processes are the articles to be welded firmly pressed together during the welding operation by one or both electrodes, for the purpose of favoring welding. Hitherto either no pressure has been exerted at all, or it has been exercised at a certain distance from the place of welding, or at all events not centrally direct upon the electrodes pressing on the place to be heated. In short, hitherto direct electric welding pressure has never been exercised by means of the

electrodes located in the direction of the current directly above the surface or point being welded.

For carrying out the new process various apparatus may be employed, as the necessary pressure may be exerted at the place suitable for producing or transmitting pressure; *e. g.*, with a press of welding by the aid of any of those technical means which are either direct or by means of indirect transmission by levers. Or it may be by means of simple hand levers, that is to say, by means of direct or indirect manual power.

In the accompanying drawing

Fig. 1 is a view illustrating the welding of two metal sheets of equal thickness, intermittently or at certain spots only.

Fig. 2 is a front elevation and

Fig. 3 a side elevation of a device which may be employed for continuous welding, the pressure being exerted by roller electrodes, whereby the advancing series of single points of the seam to be welded is united to a whole with a minimum consumption of current.

Fig. 4 illustrates the method of welding the longitudinal seam of a cylindrical or conical hollow article according to my new process.

Fig. 5 is a side elevation of a welding device (also illustrated in part in Fig. 1) according to which the pressure is exercised by pin shaped electrodes, the form of which may be suited to the particular purpose in view, and which may be adapted to work on the smallest possible surface of contact.

Fig. 6 shows two forms which may be adopted for the ends of the contacting electrodes.

As Fig. 1 shows, the two sheet metal or other bodies, the edges of which lie upon each other, are introduced between the two electrodes *a b*. Of the latter the one, somewhat prior to welding or only during the welding operation, is pressed upon the other, as the arrow shows; or both electrodes may be caused to exert pressure on the subjects to be welded.

For continuous welding of longitudinal, cross and circular seams, the device shown in Figs. 2 and 3 of the drawing may be advantageously employed.

In the two conductors *c d* (Fig. 3), forked members *e f*, making intimate contact with the conductors, are introduced, each furnished with a removable roller electrode *g* and *h*; or, if desired, only the lower roller electrode, for instance, may be capable of being removed. Or the lower or upper electrode may be formed as movable roller and the other electrode forms a stationary conductor.

The roller *g* of the upper conductor *c* is keyed to an axis *i* carrying a spur wheel *k* to which the motion of a suitably mounted hand-wheel *l* can be transmitted by means of a spur wheel *m*. Or the hand-wheel may be mounted directly on the shaft *g*, without the use of any intermediate gear-wheels. Or the axis *i* may have on the other end also a spur or bevel wheel, or pulley or the like for driving the roller electrode *g*, should it be desired to auto-

Cancelled by letter May 10/04

matically advance the object being welded by means of motor power. The purpose of the hand-wheel is to accelerate or decrease the speed of rotation of the roller *g*, as may be required, and in general to actuate the roller by hand for any purpose. The axis *i* may, of course, be caused to move slower or faster in the case of mechanical power, by any other suitable means. The upper part of the fork carrying the electrode roller *g* is here shown as constituting a toothed rack *n*, in which engages a pinion *p* carried by the conductor *c* by means of a ring-holder *o*. The pinion *p* is keyed to the axis *q*, which carries a hand lever *r* at its outer end. By raising or depressing the lever *r*, the upper roller electrode *g* may be separated from or advanced towards the lower roller electrode *h*. Furthermore by raising or depressing the forked piece *f* in the conductor *d* the lower removable roller *h* may be adjusted higher or lower.

If now the ends of the objects to be welded are introduced between the two roller electrodes *g h* and the circuit closed, continuous welding may be undertaken, that is to say, an uninterrupted welded seam made, whereby the upper rotary roller electrode *g* may be pressed with any required degree of pressure upon the lower stationary (or rotary) roller electrode *h*, so that the two ends of the material to be welded are firmly connected with each other.

Instead of the objects to be welded being introduced gradually between the electrodes, the electric welding apparatus may be arranged to slide relatively to the stationary objects.

Thus if it is required to weld, for instance, sheets of metal only at particular places, the apparatus shown in Fig. 5 may be advantageously employed, the electrodes *a b* having the form of pins. The lower electrode *b* is then inserted in the conductor *d*, whilst the upper electrode *a* is carried by an arm *s* and by means of a hand-lever *t* carried by said arm *s* can be turned on the shaft *u* in such manner that the points of the electrodes *a b* approach and recede from each other. If then two superposed sheet metal ends to be welded together are introduced between the electrodes and the latter then firmly pressed together and the circuit closed, a small round, very sharply defined place of welding is caused which perfectly answers the purposes of a rivet. In this event, also, especially in the case of thin vessels which are not required to withstand great pressure, the pressure on the place of welding may at the right moment be exactly regulated or kept within the proper limits.

Having now particularly described and ascertained the nature of my said invention and in what manner the same is to be performed, I declare that what I claim is:

1. The process of electric welding, consisting in employing the electrodes not only to conduct the current to the objects being welded, but also to exert a regulable pressure on the same, substantially as described.

2. An electrode apparatus for electric welding, comprising two electrodes between which the objects to be welded are introduced,

Cancelled by letter May 10/04.

and means whereby one of the electrodes can be approachd to and receded from the other, substantially as described.

3. An electrode apparatus for electric welding, comprising two roller electrodes between which the objects to be welded are introduced, and means for pressing the electrodes to the work, substantially as described.

4. An electrode apparatus for electric welding, comprising two roller electrodes between which the objects to be welded are introduced, means for pressing the electrodes to the work, and means for rotating one or both of the rollers for the purpose of advancing the work in its path between the electrodes, substantially as described.

AMENDMENT.

In the Canadian Patent Office, Application of Johann Harmatta, Electric Welding, Serial No. 108,990, Filed December 1/03.

Hon. Commissioner of Patents,
Ottawa, Ont.

Sir:

Cancel the present claims and substitute therefor the enclosed claims. Duplicate extra copies of the claims are herewith presented.

It is requested that on page 1, line 12, and on page 4, line 5,
C. after "sheets" the following language be inserted—from about two millimeters in thickness downward —.

It is believed that this amendment properly limits applicant's invention with regard to known processes, and that the application is now in condition to be passed to issue.

Respectfully submitted,

MARION & MARION,
Attorneys.

G./M.

CLAIMS.

1. The process of electrically welding thin metallic sheets and the like, from about two millimeters in thickness downward, consisting in first pressing intimately together the two superposed metallic objects at the very point, in which the welding joint is to be formed, and then, whilst maintaining the intimate pressure, heating the objects by passing an electric current through them exactly at said point, in which the welding is to be effected, substantially as set forth.

2. The process of electrically welding thin metallic sheets and the like from about two milimeters in thickness downward, con-
D. sisting in superposing the metallic sheets and the like, exerting on said thin sheets and the like before and during the welding operation a pressure limited to a material point, and passing for a short moment a current also limited to said material point through said thin sheets and the like, substantially as set forth.

3. The process of forming seams with thin sheets and the like from about two millimeters in thickness downward, consisting in pressing together the parts to be welded in a series of points consecutively, and, whilst maintaining the pressure in said consecutive points, passing an electric current for a short moment exclusively through said points, substantially as set forth.

Amendment Filed with letter C. Nov. 7/04.

All communications should be addressed to "The Commissioner of Patents," "Ottawa." When writing on this subject refer to No. 108,990.

Dominion of Canada,
Department of Agriculture,
Patent Office,
Ottawa, November 9, 1904.

Sir,

I am directed to acknowledge the receipt of your letter of the 7th instant, with enclosures, on the subject of Johann Harmatta's Application Serial No. 108,990 for "Electric Welding" (Case 1), and in reply inform you that the same has been referred to the Examiner.

I have the honour to be, your obedient servant,

W. J. LYNCH,
Chief of Patent Office.

To Messrs. Marion & Marion,
Montreal, Que.

Patent Office, Canada,
Ottawa, Feb. 25, 1905.

Johann Harmatta, per Messrs. Marion & Marion, Montreal.

Please find papers herewith enclosed, and below a communication from the Examiner in charge of your application, Serial No. 108,990 for "Electric Welding."

GEO. F. O'HALLORAN,
Deputy Commissioner of Patents.

Any communication respecting this application should give the serial number and should be addressed to "The Commissioner of Patents, Ottawa."

It is contended that the amended claims do not overcome the pertinency of the Thomson Patent of record, No. 347,140.

This patent described a process wherein the metal pieces to be joined are first held together by mechanical pressure devices and then while in intimate contact under such pressure an electric current is passed therethrough, exactly at the point of welding.

In Thomson's patent No. 375,022 of record initial pressure is also applied, and, whilst this pressure is maintained, the current is turned on and fusion takes place.

The thickness of the sheets to be welded is not material to the claims, as the conditions of application of the pressure and the size of the current passed is easily regulated and modified to suit the material operated upon.

A. C.

Patent Office, Canada, Nov. 16, 1905.

Johann Harmatta, c/o Marion & Marion, Montreal, Canada. "Improvements in Processes of Electric Welding," Serial No. 108,990.

Hon. Commissioner of Patents,
Ottawa.

Sir:

Responsive to the Official action of February 28, 1905, in the above entitled matter, the duplicate papers are herewith returned, with duplicate copies of the amended claims.

It is contended that the Thomson Patent of record No. 347,140 does anticipate the welding process applied for. In the patent No. 347,140 there is no question of the welding of sheets of very thin material (from about two millimeters in thickness downwards), and by his method of welding such *sheets of very thin material* (from about two millimeters in thickness downward) applicant *solves a problem* which until now was considered as quite *insoluble*.

The U. S. Patent No. 347,140 only speaks of the joining into one continuous length of *sections* of wires—as of copper and its alloys, iron, silver, gold, &c.,—by holding said sections in contact at the point of union and *simultaneously* passing a current of electricity of suitable strength through the joint.

D.

Similarly, in the U. S. Patent No. 375,022 there is only question of welding *bars* of metal together by first *abutting* the bars to be welded, applying a moderate pressure to force them together, passing the welding-current through the junction of the pieces and subsequently to an incipient welding, *increasing the pressure*.

As to be seen, in the named two United States Patents 347,140 and 375,022 there is no question of affording a quite *intimate contact* BETWEEN VERY THIN *sheets of iron*, before the electric current is led to said sheets so as to weld the same together. Besides, in the method forming the subject-matter of the U. S. Patent No. 375,022 a second pressing action is exerted in order to complete the welding process after the heating of the materials has already taken place, quite in contradiction with the new process applied for. Furthermore, applicant does NOT lead the electric current in SIMULTANEOUSLY with *exerting a pressing* action; but, on the contrary, in the process of applicant the pressure is IN ADVANCE with regard to the welding action of the electric current *from the beginning* and also *during the whole duration* of the process.

It is quite certain that never welding trials with very thin sheets of metal—for example, of 0.3 mm thickness—have been effected according to the processes of the U. S. Patents No. 347,140 and 375,022. If such trials had been made by Thomson before the ap-

D.

plication of his U. S. Patent some hints would have been given about the absolute necessity of keeping the pressing action always in advance of the welding proper, because if one does not proceed in this way, a burning through of the thin materials to be welded is unavoidable. It is true that Thomson has provided pressing

means, but he does *not* use said means *in the same manner* as applicant and *besides not for pressing together very thin metal sheets* from about two millimeters thickness downward.

The inventor was occupied during quite a number of years with the electric welding and tried to weld together very thin sheets also with the help of the principles stated in the U. S. Patents 347,140 and 375,022, but he obtained no practical results. Sometimes only an apparently good welding was obtained, but in the majority of cases the thin materials were burnt through and showed holes like a sieve, said holes being produced by electric sparks generated between the metallic surfaces in imperfect contact, and if a welding of such thin sheets could be obtained at all, the material was very much weakened at the place welded, so that said materials could not be used for practical purpose.

Only after long and repeated experiments the inventor, which during its trials found that a heating of the thin materials before the welding operation proper, that is, before the leading in of the

D.

electric current, must be avoided *under all circumstances*, discovered a way or method which permits a welding together of such thin sheets being effected with absolute certainty and reliability, *i. e.*, without a failure being possible.

It is quite true that with the devices of Thomson the eventual possibility existed to work in the same manner as applicant, but as a matter of fact nobody has worked in the same way as applicant and no one before applicant WAS ABLE *to weld so very thin metal sheets* together with absolute reliability, that is, without a burning through or damaging of the very thin metallic sheets being possible.

It is quite remarkable that in all the specifications cited by the Canadian Patent Office there is only question of the electric welding of objects, which can also be welded in an ordinary smithy fire, but in said former specifications absolutely nothing is said about the electric welding of very thin sheets of metal which can not be welded in the fire of a smithy. Therefore, the applicant is entitled to believe that no one before him devoted his attention to the welding of *thin sheets of metal* from about two millimeters in thickness downward, specially on an industrial scale. Consequently, nobody before the applicant was able to discover the fact that in welding very thin metallic sheets, the *pressure must* still be IN ADVANCE with regard to the welding.

D.

Favorable reconsideration and an early allowance is requested.

Respectfully submitted,

MARION & MARION,
Attorneys for Applicant.

Montreal, Canada, November 15, 1905.

D.

W. J. LYNCH,
Chief of Patent Office.

To Messrs. Marion & Marion,
Montreal, Que.

Patent Office, Canada,
Ottawa, January 11, 1906.

Johann Harmatta, per Messrs. Marion & Marion, Montreal, Que.

Please find papers herewith enclosed, and below a communication from the Examiner in charge of your application, Serial No. 108,990 for "Electric Welding" (Case 1).

GEO. F. O'HALLORAN,
Deputy Commissioner of Patents.

Any communication respecting this application should give the serial number and should be addressed to "The Commissioner of Patents, Ottawa."

Case re-examined on amendments filed November 16, 1905.

It may be remarked that limiting the welding to thin sheets about two millimeters and less in thickness and which can not be welded in the fire of a smithy does not give patentability to an old process.

The Office report of February 28, 1905, applies pertinently to the claims submitted. Said claims are moreover substantially the same as the rejected claims.

The former citation shows methods of welding by first pressing together the articles to be welded, then passing the electric current through them at the points to be welded while still maintaining the pressure. This method, without invention, could be used for lap welding sheets of metal as well as rods.

In reply to applicant's attorney's letter filed on the above date, the Office cites the following United States Patents disclosing methods and means for electrically lap welding metal sheets or bars.

These patents anticipate the amended claims:

690,958 to Hunter, January 14, 1902,
670,808 to Perry, March 26, 1901,
403,708 to E. Thomson, May 21, 1889,
423,735 to C. L. Coffin, Mar. 18, 1890,
437,571 to C. L. Coffin, Sept. 30, 1890,
444,928 to E. Thomson, Jan. 20, 1891,
447,104 to M. W. Dewey, Feb. 24, 1891.

AMENDMENT.

In the Canadian Patent Office, Application of Johann Harmatta, Electric Welding, Serial No. 108,990, filed Dec. 1/03.

Hon. Commissioner of Patents,
Ottawa, Ont.

Sir:

Responsive to the Official action of January 11, 1906, the duplicate specification and drawings are herewith returned, accompanied by duplicate extra copies of the rewritten claim.

E.

REMARKS.

None of the cited United States patents make a disclosure of electric welding of sheets of two millimeters in thickness, or sheets of even less thickness. Neither is there a disclosure made of placing metallic sheets one upon another and pressing the same together before conducting an electric current through them in such manner that a perfect contact of the parts to be welded is secured.

In the United States patent No. 690,958, cited, the overlapping tin ends are held in the proper position *before* conducting the electric current through, but they are not *pressed* together, as disclosed in the present application. If in this patent the tin ends were pressed together *before* heating, as hard as in the process disclosed by applicant, the small bosses formed in the tins before this step

would be pressed out again. From Claim *3* of this patent it can be clearly seen that the pressure is increased during the welding.

In United States Patent No. 670,808, cited, the welding pressure is only applied when the metal has become heated and soft by the passage of the electric current (see page 1, Claim *2*, lines 60 and 65). In that patent there is the disclosure of welding material having a large cross section, and there is no disclosure of thin metallic sheets. The material being acted upon is different from applicant's disclosure, so that the patent is not as pertinent as at first it would seem to be.

In United States Patent No. 103,708, the welding pressure is only applied after the heating of the material, and not before and during the heating (see page 1, Claim 1, lines 15 to 17). This also applies to United States Patent No. 423,735 (see page *2*, Claim 1, lines 8 to 11) and United States Patent No. 437,371 (see page 1, Claim *2*, lines 98 to 100).

E. In United States Patent No. 444,928 (page 1, Claim 1, lines *35* to *38*) a disclosure is made that the metallic sheets are pressed together, and that the electric current is conducted through them simultaneously. But, there is no disclosure that the pressure is such that a complete surface contact at the place of welding is obtained. It is natural that a certain pressure must be exerted at every welding before the heating, so as to keep the material together in the right position, but the process of applicant is based upon the fact that in operating on thin metallic sheets, a pressure must be exerted at the place of welding so strong that *all unevenness of the metallic sheets* is removed, so that a contact of the complete surface takes place.

As a new technical result obtained by this slight difference, it is submitted that all danger of burning or perforating the material is avoided. Applicant has ascertained through experiments that the minute perforations of the material in electric welding are caused by the formation of very small arcs, or by the effect of the piercing of small sparks. This burning of the material and its perforation always took place where the two thin metallic sheets were to be welded when the sheets were not brought into the closest contact before the current was switched on. It is believed that this fact was not known until now, and that this fact being ascertained, the process based upon it is new.

In United States Patent No. 447,108, the pressure is increased during the welding (see page 1, Claim *2*, lines 67 to 70). It is expressly stated that the material is first heated and made soft by the electric current, and then the pressure is increased. This is different to what is maintained to be new, and the reference therefore is not a pertinent one.

E. If the Examiner is of the opinion that the claim now presented is allowable, the description will be redrawn to conform to the claim.

The Examiner's most careful attention is requested to this single claim, which specifically defines applicant's invention.

Respectfully submitted,

MARION & MARION,
Attorneys for Applicant.

C/W

Having thus fully described my invention, what I claim as new and desire to secure by Letters Patent, is:

1. The process of electrically welding thin metallic sheets and the like, from about two millimeters in thickness downward, which can not be welded in the fire of a smithy, consisting in first pressing intimately together the two superposed metallic objects at the very point, in which the welding joint is to be formed, and then, whilst maintaining the intimate pressure, heating the objects by passing an electric current through them exactly at said point, in which the welding is to be effected, substantially as set forth.

2. The process of electrically welding thin metallic sheets and the like from about two millimeters in thickness downward, which can not be welded in the fire of a smithy, consisting in superD. posing the metallic sheets and the like, exerting on said thin sheets and the like before and during the welding operation a pressure limited to a material point, and passing for a short moment a current also limited to said material point through said thin sheets and the like, substantially as set forth.

3. The process of forming seams with thin sheets and the like from about two millimeters in thickness downward, which can E. not be welded in the fire of a smithy, consisting in pressing together the parts to be welded in a series of points consecutively, and, whilst maintaining the pressure in said consecutive points, passing an electric current for a short moment exclusively through said points, so as to keep the pressing action in advance of the electric heating during the whole welding operation, substantially as set forth.

All communications should be addressed to "The Commissioner of Patents," "Ottawa." When writing on this subject refer to No. 108,990.

Dominion of Canada,
Department of Agriculture,
Patent Office,
Ottawa, Nov. 9, 1906.

Sir,

I am directed to acknowledge the receipt of your letter of the 7th instant, with enclosure, on the subject of Johann Harmatta's Ap-

plication Serial No. 108,990 for "Electric Welding," Case 1, and in reply inform you that the same has been referred to the Examiner.

I have the honour to be, your obedient servant,

W. J. LYNCH,
Chief of Patent Office.

To Messrs. Marion & Marion,
Montreal, Que.

Patent Office, Canada,
Ottawa, November 26, 1906.

Johann Harmatta, Esq., per Messrs. Marion & Marion, Montreal, Que.

Please find papers herewith enclosed, and below a communication from the Examiner in charge of your application, Serial No. 108,990 for "Electric Welding" (Case 1).

GEO. F. O'HALLORAN,
Deputy Commissioner of Patents.

Any communication respecting this application should give the serial number and should be addressed to "The Commissioner of Patents, Ottawa."

Case reconsidered in view of applicant's attorneys' letter of November 7th, filed November 9, 1906, and the amendments submitted therewith.

The following report may be considered in two parts:

Part 1 dealing with the subject-matter of the specification now on file, filed with applicant's attorneys' letter of July 9, 1904. And part 2 dealing with the patentability of the subject-matter disclosed in the original specification and drawings.

Firstly. The claim may be rejected on the United States Patents of record Nos. 447,104 to Dewey and 444,928 to Thomson.

The tenor and gist of applicant's alleged invention, as interpreted by the Office from his specification above mentioned and principally from his various letters, is as follows: It would appear that his alleged invention consists in welding thin sheets of metal such as used in kitchen ware by pressing said sheets together between electrodes with very great pressure. This pressure being so great that all irregularities and unevenness will be pressed smooth and flattened out of the sheets and that all air space and interstices between the sheets will be eliminated. Then a current is passed between the electrodes whereby the metal is softened and welding takes place as the pressure is maintained but not increased.

Applicant's attention is directed particularly to United States

Patent No. 444,928 to Thomson, page 1, lines 34 to 39; lines 50 to 54; 90 to 95; page 2, lines 1 to 11; and 90 to 94. His attention is also directed particularly to Figures 1, 2 and 3 of the drawings and to Figures 2 and 3 of applicant's original drawings.

Now it will be seen that Thomson's process and apparatus are intended for welding thin sheets of metal. This is done by intimately pressing the sheets together and then passing an electric current through them.

His apparatus and applicant's above referred to would necessarily work in substantially the same way. Thomson's rolls R and R' would press the sheets together with a pressure which increases to a maximum and then electric current will be passed between the electrodes and welding will take place without increasing the pressure. Thus it is seen that Thomson's apparatus provides for eliminating all irregularities and air space between the sheets to be welded. His electrodes are adjustable to and from each other to regulate the amount of pressure required.

However, as Thomson has not made a feature of his specification in using extreme pressure, it may be contended that applicant, in the above amended specification, disclosed certain patentable novelty. This novelty might be considered as pointed out in a claim read somewhat as follows:

> "The process of welding a plurality of metal sheets consisting in exerting a maximum pressure by means of electrodes on said sheets, thereby flattening, smoothing out and eliminating all irregularities and intimately pressing said sheets together whereby air space and interstices between said sheets are eliminated, subsequently passing an electric current through the sheets thus softening and welding same while maintaining but not increasing the pressure on the sheets."

Such a claim would be very narrow and it is doubtful if the courts would maintain it as being valid over the patent of Thomson for it is considered that the Thomson patent approaches so near to the claim that any one skilled in the art without invention would use such a process as pointed out in the above claim. However, as it is the duty of the Office to give an applicant the benefit of any doubt as to patentability, the above claim has been suggested.

Secondly. As above pointed out there appears to be very narrow patentable matter disclosed in applicant's specification and drawings filed with his letter of July 9, 1904. But on a thorough examination and consideration of this case as originally filed, and the amendments, it is held that applicant did not disclose any patentable process in his original specification and drawings, hence consideration can not be given to any claim such as suggested which may be submitted.

In view of the fact that there was no patentable novelty originally disclosed in the application as filed December 1, 1903, this application is held rejected.

The Office has gone very fully into the consideration of this case so that applicant, if he so desires and can in view of the Petition and Oath required file a new application embodying the very limited doubtful patentable matter.

UNITED STATES PATENT OFFICE.

ADOLPH F. RIETZEL, OF LYNN, MASSACHUSETTS, ASSIGNOR, BY MESNE ASSIGNMENTS, TO THOMSON ELECTRIC WELDING COMPANY, OF LYNN, MASSACHUSETTS, A CORPORATION OF MASSACHUSETTS.

CONSTRUCTION OF SHEET-METAL UTENSILS.

1,041,351. Specification of Letters Patent. Patented Oct. 15, 1912.

Application filed December 26, 1906. Serial No. 349,347.

To all whom it may concern:

Be it known that I, ADOLPH F. RIETZEL, a citizen of the United States, and a resident of Lynn, in the county of Essex and State of Massachusetts, with post-office address Lynn, Massachusetts, have invented certain new and useful Improvements in the Construction of Sheet-Metal Utensils, of which the following is a specification.

My invention relates to the manner of securing bail ears, handles or other attachments to the bodies of sheet metal utensils or similar articles. The usual method of securing such attachments is to rivet the ear, handle or other device to the plane surface of the utensil body which, in practice, is a more expensive method of attachment than that provided by my present invention and, moreover, does not form a perfect union such as is desirable when the utensil with its attachment is subsequently subjected to an enameling process. It has also been proposed to secure the attachment to the sheet metal body by indenting the sheet metal attachment or the surface of the body to which it is united to form electrical contacts of restricted area which will localize the heating electric current passed through the metal and bring the parts to the requisite welding temperature so as to permit the parts to be welded by pressure as in the well-known electric welding process. The latter method of attachment requires a special preparation of the parts to be united which it is one of the purposes of my invention to dispense with, while at the same time securing a firm union of the attachment to the utensil body.

Briefly stated, my invention consists in attaching the bail ear or other sheet metal attachment by welding it on its plane face directly to the rounded edge of the utensil body, said rounded edge affording on its point of contact with the plane face of the metal attachment, the contact of restricted extent which, by localizing the current and opposing its free passage, brings the parts quickly to the welding temperature preliminary to the application of the welding pressure. To assist in the localization of the heating effect, the ear or other attachment may be formed with two or more planar projections of restricted area which touch the rounded edge and form in a way heat localizing projections whose office is similar to that of the projections formed on the face of the attachment by indenting the metal as in the previous method of attachment. It is, however, within my invention to dispense with the use of such planar projections, the localization of the heating effect being then due simply to the fact that the plane face of the attachment makes contact with the edge on a rounded surface.

My invention consists further, broadly stated, of a sheet metal utensil having the bail ear or other attachment welded to the edge of the utensil body at a plane face of the attachment.

In the accompanying drawings, Figure 1 is a section through one side of the body of a sheet metal utensil showing the manner in which the bail ear or other attachment makes contact with the rounded edge. Fig. 2 is a plan of a bail ear of the preferred form. Fig. 3 is an end view of the attachment looking toward the end which has the planar projections. Fig. 4 shows the utensil and attachment as assembled between the pressure jaws or blocks of an electric welding apparatus by which the attachment may be welded to the edge of the utensil. Fig. 5 is a face view of the two welding jaws or blocks and illustrates the concave and convex form given to the surfaces in order that they may properly engage the circular edge of the utensil.

Referring to the drawings, 1 indicates the sheet metal body of a utensil having a rounded edge 2 usually employed for the purpose of reinforcing the metal at the edge.

3 is the attachment formed of sheet metal and shown in Fig. 2 as consisting of a bail ear, although as will be obvious, the attachment might be a sheet metal handle of any form or any other attachment which it is desired to secure to the utensil body.

In the preferred form of attachment, the same is provided with planar projections 4 which are adapted to restrict or lessen the area of contact between the attachment and the edge of the utensil. When so formed the union of the attachment and the rounded edge is by the plane faces of said planar projections 4, only, the intermediate portion being free of union with the edge. Ordinarily, it is preferred to use two or more planar projections as described, since the same being located at a considerable dis-

2072

tance apart, form a more secure means of attachment. It would, however, be within my invention to make the union extend continuously across the face of the sheet metal attachment, the same being curved to properly engage the edge of the utensil in a continuous circumferential line. In any case, however, it will be seen that the plane face of the attachment forms a tangent to the curve of the edge of the utensil and thereby gives a restricted or limited area of contact for the passage of electric current used in the welding, thereby localizing the heating in order to quickly and economically heat the parts to a welding temperature at the point of union.

The actual operation of welding is conveniently carried on in an electric welding machine, parts of which are indicated in Fig. 3 diagrammatically. In this figure the contact and pressure jaws or blocks shown at 5, 5′ are adapted to receive the edge of the utensil and the attachment 3 assembled as shown. The parts being lightly compressed together by the operation of the pressure jaws, electric current is permitted to flow and bring the parts to a proper welding temperature after which the quick application of heavy pressure completes the weld and forms a strong union between the attachment and the utensil body on the edge of the latter.

In Fig. 4 the usual transformed secondary of which the pressure blocks 5, 5′ constitute the electrodes is typified at 6, while 7 typifies the transformer primary. 8 is a stop which assists in properly locating the utensil between the jaws 5, 5′. When the utensil body is round at its edge, the jaws 5, 5′ should be properly formed as shown in Fig. 5, the one with a convex face to engage the inside of the utensil body and the other with a concave face to properly engage the curved edge of the attachment.

What I claim as my invention is:

1. A sheet metal utensil having its attached bail ear or other sheet metal attachment welded to a rounded edge of the utensil body by its plane face, as and for the purpose described.

2. A sheet metal utensil having a bail ear or other attachment welded to the edge of the utensil body by two or more projections in the same plane as the main body portion of the ear.

3. A sheet metal utensil having a rounded edge to which the bail ear or other attachment is welded at the plane face, of two or more planar projections extending from said attachment.

4. The combination with a sheet metal utensil, of a rounded reinforced edge on said utensil and a bail ear welded to said edge directly by the plane surface of said ear.

Signed at Lynn in the county of Essex and State of Mass. this 28th day of Nov. A. D. 1906.

ADOLPH F. RIETZEL.

"Defendants Exhibit No 72, Inc Britt Letter 4/20/14" Thomas Durant, Notary Public

THOMAS DURANT NOTARY PUBLIC DISTRICT OF COLUMBIA

Dear Sir:-

I have been expecting to be in your neighborhood and call on you regarding the Harmatte Patent Situation.

The case was filed against the Barney and Berry Co., suit being instituted by the Tompson Co., for enfringement on the Harmatte Patent, and was defended by the Toledo Elec. Welder Co. at Boston last month.

As I understand, the case was set for the week before April 1st, and was postponed until April 1st. I will try to give you an idea of just what happened.

I was sent for hurriedly, at the last moment, and when I got down there, I found that the case was to be tried the same day. I stayed there from the 1st of April until the following Friday evening, when the evidence was all in, and I watched matters pretty close, and I am very much inclined to think that it is a sell-out proposition.

I had quite a talk with Mr. Warren, after we had been there a couple of days, and I found out that he had been down at Brooklyn, with the Universal people, for about three weeks, and the final wind-up was that he could not get together with the Universal people at the early part of the game, and consequently the Tompson people had this case postponed one week. This is what Mr. Warren tells me.
Apparently the Tompson people were very much interested in having the Toledo and Universal people get together.

However, it began to look a little better after the case had been postponed and set forward a week, and Mr. Warren tells me that the night before the case was to be tried, or rather the day before, he had a contract all written up an signed by Lankman of the Universal Co. which was based on a nominal fight on the Patent, and then the Patent would be sustained, and the Toledo Co. would place machines under a rental basis and a percentage of the rental was to go to the Tompson people and

the Universal people. He outlined all the terms to me.

As this was entirely satisfactory to the Universal people, apparently, they signed it through Mr. Lockman, and he then went to the Tompson Co. at Lynn, Mass. and everything appeared to be satisfactory to them, although as I understand it there was no signature passed in that case, as the deal was entirely between the Toledo and the Universal.

When he returned, however, to Boston, to be present at the case, he found that the Universal people were not going to stand by the contract, and they advised him that Mr. Lockman had no business whatever signing such a contract.

Now, whether this was just a matter of safety and they were afraid that the proposition would be brought into the court and used as evidence against them, I cannot say, but it certainly upset Mr. Warren very much when he found out that his agreement apparently was not holding.

The last day of the case I was talking with Warren and he seemed to feel so blue that he was about ready to give up, and he told me that if they lost this case, they were going to clean up every outstanding account they had, and then if there was anything more doing, the customers would have to do it, in other words, he proposed to get in shape to get out of this welder business, and my opinion of the whole situation is that his intention is to clean up all outstanding accounts and then if he can make a deal with the Tompson people, whereby he will continue under their protection, all right, well and good, the customers can get nothing of him and if he cannot, he will try and sell out to the Tompson Co.

Another thing which surprised me was, that I was in Hamilton, O., which is close to Cincinnati Saturday, and I got word that the Toledo Cole plant was shut down due to a strike. This seemed rather peculiar on the face of it, because there are about 75% of the machinists and Hamilton, which is the biggest machine tool center in the world, and the fact that these men are out of work, would indicate that it was a very poor time for a bunch of men to go on strike for an increase of wages. I am therefore inclined to think that this strike was more with a view of closing the plant down for the time being than it was to get anything else. I think that the strike was organized from the office rather than by the men.

Of course, I can see where the Tompson people would not sign up any contract with the Toledo Co. at that particular instance, because proving in the court that such an arrangement had been made would have a tendency to prejudice the judge in favor of the Patent not being valid.

as I understand it now, the evidence on the evidence obtained, will be considered along in the middle of June.

In connection with this matter, I want to say that they are on the stand, and the question was asked me how long I had been in the electric welding business, and I will then ask a the 5th of September, 1911. The attorney for the Union people then asked me if I had ever seen or that any [illegible] previous to this time, and I said that he [illegible] I had, and immediately Mr. Fish, who handled the matter for the Company objected, and said that it was not any part of the defendant's case to prove the gravity of the act. The Court sustained the objection, and the objection was sustained, consequently that was all the evidence that was put in on that matter at any time.

There was no effort on the part of the Union people so far as I could find out, to prove that the [illegible] injured. They were never inclined to say and prove that the [illegible] was not legally allowed, that is, due to the fact that it had been changed so much, and also a disposition on the part and also that the [illegible] which had been used by the Company and hence [illegible] was not actually a fair ballot proposition, but I have talked possibilities, as they were trying to make a [illegible] matter, or rather a [illegible] by a series of words, and I asked Mr. Edwards of the Edwards, Ingram & Bowles Co., [illegible] whether they were trying to prove that this ballot was not actual, or whether they were trying to prove that the Company & Company Co., were not using the ballot as it had been applied for.

Edwards said that they were trying to prove that the ballot was not valid, and I told him that I thought that they were going at it in rather a peculiar way.

However, he said that he thought they had before them an [illegible] chance to win. This is the situation. My opinion is that they've got a chance of a chance to win, considering the evidence that has presented, and also considering the [illegible] of the Court towards the Company Co. The fact of the matter is, the Court asked for advice and received advice and counsel from Mr. Clark, and as a matter would have the impression that Mr. Clark was a [illegible] the Court rather than the Judge.

I am therefore sure such of the opinion that somebody else is going to have to fight this case if it is ever fought.

I want to know whether this matter can be taken up with any [illegible] of Burlington, or that the case could be [illegible] provided the Company Co. and Clark case, and the Union people do not agree to put up a fight.

I am quite [illegible], so far [illegible], to see that we are going [illegible] a fight to finish the case instead of simply [illegible] failure. If you take any [illegible] which you give me will help me to get this thing in shape. I

would be pleased to hear from you, and hope this long letter h
not taken up too much of your valuable time.

Thanking you for your past favors, I am

Very respectfully yours,
The National Elec. Welder Co.

Board of Examiners-in-Chief Decision in Harmatta vs. DeFerranti

Hearing:
December 17, 1918.
Appeal No. 2844. U. S. Patent Office. June 24, 1919.

BEFORE THE EXAMINERS-IN-CHIEF, ON APPEAL.

In the matter of the interference between the application of Sebastian Ziani de Ferranti, filed December 29, 1911, Serial No. 668,464, division of application filed May 14, 1904, Serial No. 208,034, and the patent to Johann Harmatta, granted December 3, 1912, No. 1,046,066, on application filed December 3, 1903, Serial No. 183,677. Interference No. 36,709.

IMPROVEMENT IN ELECTRIC WELDING.

MESSRS. SPEAR, MIDDLETON, DONALDSON & SPEAR and MR. MELVILLE CHURCH for de Ferranti.

MESSRS. TOWNSEND & DECKER for Harmatta.

De Ferranti has appealed from the decision of the Examiner of Interferences awarding priority of invention to Harmatta.

The invention is defined in an issue of four counts. These are as follows:

1. The hereinbefore described improved method of fastening two pieces of metal together by electrically welding them to one another at spots only of their juxtaposed or opposite faces by the application of pressure and heating current localized in such spots.

2. The herein described method of uniting two pieces of metal at a number of distinct or separate spots separated from one another by well defined areas of no union, consisting in applying pressure localized at the spots of desired union, and passing electric current through the pieces from one to the other while confining the flow of current to said spots until the union is effected.

3. The herein described method of uniting two pieces of metal, consisting in pressing them together while passing a heating electric current from one to the other and localizing the flow of current and the heating throughout the operation in a spot or spots of circumscribed or limited area as compared with the area of the immediately opposed surfaces so as to limit the union of the pieces to a spot or spots.

4. The improved method of uniting two pieces of metal at a spot or spots only in their opposed meeting surfaces, consisting in pressing the two pieces together, and passing a welding electric current from one to the other while localizing the pressure in and confining the flow of current to the spot or spots of desired union so as to produce an isolated spot or

Both parties are foreigners. Harmatta has not attempted to carry his date of invention back of his filing date in this country, December 3, 1903. De Ferranti's application in interference is a division of his application No. 208,034, filed May 14, 1904, upon which patent No. 1,148,221 was granted on July 27, 1915. To overcome Harmatta's earlier filing date in this country, de Ferranti relies entirely on the filing of a provisional application in Great Britain on May 25, 1903. The complete specification was left on February 25, 1904, and accepted August 25, 1904. Patent No. 11,921 of 1903 was granted upon that application.

Harmatta contends that de Ferranti's provisional application does not adequately disclose the invention here in controversy. Both parties have taken testimony on this question. The Examiner of Interferences found for Harmatta upon this point and also held that de Ferranti was estopped from asserting priority over Harmatta by the doctrine of Rowntree vs. Sloan, 227 O. G., 744; 45 App. D. C., 207.

De Ferranti's provisional application is particularly directed to a process of attaching turbine blades. And the object of the invention is stated to be the reduction of the large amount of metal theretofore appearing in the turbine ring to which the blades are welded, so as to reduce the flow of heat from the vicinity where the blade is welded to the ring. De Ferranti described in his provisional application several different forms or processes, some of which clearly do not come within the scope of the counts. The provisional specification did not comprise a drawing.

We find that de Ferranti's witness has fairly set forth the inferences which those skilled in the art would draw from this provisional application. De Ferranti's Exhibit No. 1 correctly shows, in our opinion, what those skilled in the art would understand this provisional application to describe. In making the structures of figures 2, 3, 5 or 7 of this exhibit as described in the provisional application, those skilled in the art would infringe the claims which constitute the counts of this interference.

Nor can this disclosure be regarded as accidental merely because the functions and advantages thereof which underlie the invention here in controversy were not appreciated by de Ferranti. They are inherent in his process as disclosed when carried out in the manner indicated in figures 2, 3, 5 and 7 of de Ferranti's Exhibit No. 1.

Nor can this disclosure be regarded as accidental merely because de Ferranti also disclosed the forms or methods indicated in figures 1, 4 and 8 of his Exhibit No. 1 which do not involve the process here in issue. When an inventor positively and definitely describes two or more structures or processes, he is not any the less a discloser and inventor of any one of these than he would have been had he disclosed only that one.

In this connection it is noted that Harmatta's application in inter-

invention when originally filed. The emphasis and claims therein were to the application of pressure to the weld through the electrodes though the present process was unmistakably disclosed.

We hold that the Examiner of Interferences erred in not finding the invention in controversy to be adequately disclosed in the de Ferranti provisional application.

Taking up the question of estoppel we find that de Ferranti appears to have first asserted claims to the present invention on December 6, 1910. As Harmatta's patent did not issue until 1912 de Ferranti is not barred by the same from prevailing here. But the counts of this interference were drawn from a patent to Rietzel No. 247,081 (928,701), which issued upon July 20, 1909. Harmatta made claims to the present invention at least as early as March 31, 1910, and an interference was declared between his application and the Rietzel patent upon April 26, 1910. If de Ferranti had been claiming the present invention at that time he would presumably have been placed in that interference. It is true that the Examiner could have taken steps toward the inclusion of de Ferranti's application in that interference at any time after December 6, 1910, when de Ferranti first laid claim to the present subject-matter. This was presumably overlooked by the Examiner. If the claims that de Ferranti advanced on December 6, 1910, had been advanced before July 20, 1910, he would not have been estopped even though the Examiner did not take steps looking to the addition of de Ferranti to the Rietzel-Harmatta interference. As it is, however, de Ferranti did not make any claim until more than a year after the issue of the Rietzel patent, whereas Harmatta did do so and has prevailed over Rietzel in an interference proceeding. We think that the reasons underlying the decision in Rowntree vs. Sloan, *supra*, apply to the present case and that de Ferranti is accordingly estopped to assert priority over Harmatta. Harmatta must therefore prevail.

The decision of the Examiner of Interferences is affirmed and priority of invention is awarded to Johann Harmatta, the senior party.

Limit of Appeal, July 14, 1919.

UNITED STATES PATENT OFFICE.

ARTHUR M. STANLEY, OF LYNN, MASSACHUSETTS, ASSIGNOR TO GENERAL ELECTRIC COMPANY, A CORPORATION OF NEW YORK.

WELDING PRESSURE-CONTACT.

1,176,614. Specification of Letters Patent. Patented Mar. 21, 1916.

Application filed January 23, 1915. Serial No. 3,946.

To all whom it may concern:

Be it known that I, ARTHUR M. STANLEY, a citizen of the United States, residing at Lynn, in the county of Essex, State of Massachusetts, have invented certain new and useful Improvements in Welding Pressure-Contacts, of which the following is a specification.

My invention has reference to electric welding by heating the surfaces of the objects to be welded by the passage of an electric current between them while they are in contact under pressure, as distinguished from welding by heating the surfaces of the objects by an electric arc formed between them and then contacting these surfaces under more or less pressure. The former process is generally spoken of as "resistance welding", because the welding heat is a function of the electrical resistance of a short portion of the objects back of the contacting surfaces, and of the transition resistance between the surfaces; while in the arc welding process the welding heat is almost entirely due to the arc formed between the surfaces.

There are two species of resistance welding, namely, butt welding and sheet welding. In butt welding, the two objects to be welded together are each tightly held in a clamp of very low resistance and high thermal conductivity and are brought into contact with moderate pressure, the current being supplied through the clamps, so that there is practically no resistance in the clamps and between each clamp and the respective welding object. The clamps are, therefore, not noticeably heated and impart no heat to the welding objects, the heat being developed solely in the welding objects at and near their contacting surfaces, and the clamps acting as current conveyers and heat dissipating means, so that the temperature of the welding objects back of the contacting surfaces is kept low. In sheet welding clamps cannot be conveniently employed and are generally not employed, and, in fact, the term "sheet welding" properly applies only to those cases where welding clamps are not employed. In these cases, as where two or more sheets are superimposed and welded together, face to face, the welding current is supplied to the sheets at the place where a weld is to be made by pressure contacts, the same as by the clamps in butt welding, with this difference, however, that whereas the clamps have a negligible resistance and a negligible transition resistance toward the welding objects, the pressure contacts being small in cross-section, have a noticeable resistance and a decided transition resistance toward the sheets.

My invention has reference to sheet welding and more particularly to the welding of sheets made of metals of low specific resistance and high thermal conductivity, such as copper, brass, aluminum and others.

Heretofore sheet welding on sheet-iron, sheet-steel and sheets of other metals of comparatively high specific resistance and low thermal conductivity has been accomplished with varying success with the use of copper pressure contacts, but it was found impossible to make successful sheet welds between copper, brass, and other like metals. The pressure contacts of copper were found to be useless when sheet-copper was attempted to be welded, because they tended to chill the sheets, which themselves are good conductors of heat, and to chill them to such an extent that with a moderate current the welding heat could not be imparted to the sheets, and when the current was raised the pressure contacts themselves became welded to the sheets.

I have found that in order to successfully weld sheet copper (which may here serve as the representative of low resistance and good heat conducting metals) it is necessary that the pressure contacts be of a material that has a considerably higher specific resistance than copper and that its ohmic resistance be sufficiently high that it may be heated by the current as much or more than the copper and then act as a barrier to heat conduction from the work; that it be a comparatively low conductor of heat for the same purpose; that it be more refractory than copper, so that it will not soften and become welded to the copper; and that it have considerable mechanical strength and not be noticeably deteriorated by exposure to air at the temperatures to which it is subjected. I have found all these characteristics combined in the metals tungsten and molybdenum, and by the use of either of them as pressure contacts I have been able to weld together sheets of copper and other metals of like properties safely and expeditiously, and without deterioration of the contacts after long continued use. It is not

2035

Defts Exhibits aaaa

necessary that the whole body of the pressure contact piece be made of tungsten or molybdenum, since it is all sufficient that the contact proper be a short piece of tungsten or molybdenum carried by any other suitable metal, which latter may be considered as a backing or carrier of the pressure contact proper. All this will more fully appear from the following detail description with reference to the accompanying drawing, in which a number of the many possible forms in which my invention may be embodied are set forth and illustrated.

Figure 1 is a side elevation of a form of welding pressure contact made in accordance with my invention. Fig. 2 is a side elevation of another form of welding pressure contact. Fig. 3 is a side elevation of the jaws of a machine carrying another form of welding pressure contacts, also suitable for brazing. Figs. 4, 5, and 6 are views illustrating the application of my invention in welding two sheets together at a single spot at a time; and Fig. 7 is a perspective view illustrating the application of my invention to continuous line welding.

In Fig. 1 the contact support 10 is rather bulky and may be made of copper, but any other metal of sufficient bulk so as to have a small ohmic resistance may be used. In the end of this bulky piece of copper is inserted the welding pressure contact proper 11, and this is made of either molybdenum or tungsten, or of any other substance which has the hereinbefore described characteristics of molybdenum and tungsten. It is inserted in the piece 10 to a considerable depth so as to be well united with the same, and only a very short piece of it projects; and it is this short projecting piece of molybdenum or tungsten which serves as the welding pressure contact in accordance with my invention. Owing to its considerable mass, the carrier prevents the welding pressure contact proper from becoming overheated. The shape of the welding pressure contact is immaterial; it may be cylindrical or prismatic or have any other cross-section, but under all circumstances it must not project beyond the carrier 10 to any considerable length. I have found that if this piece projects about one eighth of an inch, it gives very satisfactory results under most conditions; while when it projects considerably more than one eighth of an inch it generally gets too hot and imparts too much heat to the sheets to be welded, which are then liable to be burned through. In Fig. 2 the construction shown is similar to that of Fig. 1 except that in this case the welding pressure contact 16 is in the form of a button having beveled edges inserted into a recess formed in the carrier 15, and the metal of the carrier is then spun over the bevel of the contact and thus firmly holds it in place. It will be understood that in both of these constructions, in fact, in all applications of my invention, the copper or other carrier of the welding pressure contact is not intended to come into contact with the sheets which are to be welded, as will appear farther on.

In Fig. 3 the welding pressure contacts 18 of molybdenum or tungsten are inserted in the faces of jaws 17 for a considerable length and may have any suitable width, either for welding sheets together over a considerable surface in one operation, or for brazing them together.

It will be understood that the structures shown in Figs. 1 and 2 are supposed to be parts of a welding machine; that the current is conducted primarily to the carriers 10 and 15; and that the sheets to be welded together are overlapped and the overlapped portion is inserted between two such structures as are shown in either Fig. 1 or Fig. 2, or between two structures like Fig. 1 and Fig. 2. In some cases only one of these structures is used and the other necessary pressure contact is supplied otherwise. Thus, a highly successful weld can be made by the arrangement shown in Fig. 4 in which one carrier and contact 20 is constructed like that shown in Fig. 1 and the other is constructed like that shown in Fig. 2. Welding by the use of two such pieces is known in the art as spot welding, the weld only occupying a surface equal to that of the smaller of the two welding pressure contacts. The welding operation usually takes about one quarter of a second of time so that in the practical operation of spot welding the two sheets which are to be welded together are usually placed upon one of the welding pressure contacts and the other welding pressure contact is quickly brought down upon the sheets in alinement with the other and is almost immediately thereafter withdrawn. This is the practical operation, which is well known in the art as spot welding of sheet iron. Usually and preferably one of the welding pressure contacts is broader than the other, since in this manner the work does not become perceptibly marred.

In Fig. 5 I have illustrated the welding of a sheet of copper 31 to a sheet of steel 32. In this case the welding pressure contact 33 which comes to bear upon the copper sheet must be either molybdenum or tungsten in accordance with my invention, while the pressure contact piece 34 upon which the sheet steel rests may be of copper.

In Fig. 6 I have illustrated an arrangement in which only one of the welding pressure contacts 51 is a terminal of the circuit that carries current to the work. The other terminal 53, is a block of any desired shape in contact with one of the sheets of the cou-

20096

Welds Exhibit a a a a

ple which is to be welded together, and 52 represents the plunger of a punch which presses the two sheets against the contact 51 and thus localizes the weld.

Fig. 7 illustrates my invention in its application to line welding. The roller 60 of copper or other good conductor has a slightly projecting rim 61 of molybdenum or tungsten which constitutes the welding pressure contact and two sheets 63, 64 of copper are supported upon a table 62 which constitutes one of the terminals, the roller 60 being the other terminal. As this roller is moved along the overlapping edges of the two sheets, current being supplied to the apparatus as indicated, a welded seam is formed expeditiously, the speed of the roller being gaged according to the current supplied and according to the thickness of the sheets.

It is quite practicable to weld together three or more superposed sheets of copper or other low resistance material if the rule is observed that the welding pressure contacts must project from the carrier to a greater distance as the number of superposed sheets increases; but under all circumstances the projection of the welding pressure contact must be very short, within the range of about one-eighth to one-fourth of an inch.

It should be understood that the constructions herein shown and described may be changed in form, size and proportions without deviating from my invention; and wherever in the appended claims the metal tungsten is recited, it is to be understood that the metal molybdenum is the equivalent of the same.

What I claim as new and desire to secure by Letters Patent of the United States, is:—

1. A sheet metal welding pressure contact having the described characteristics of tungsten and molybdenum.

2. A sheet metal welding pressure contact having the described characteristics of tungsten and molybdenum and a carrier for the same having low electrical resistance and large heat radiating surface.

3. A sheet metal welding pressure contact of refractory high resistance material which is only slightly affected by the oxygen of the air at high temperature, and a carrier for the same having low electrical resistance and large heat radiating surface.

4. A sheet metal welding pressure contact of tungsten.

5. A sheet metal welding pressure contact of tungsten and a carrier for the same having low electrical resistance and large heat radiating surface.

6. A sheet metal welding pressure contact of tungsten and a carrier for the same of copper having large heat radiating surface.

In witness whereof, I have hereunto set my hand this 22nd day of January, 1915.

ARTHUR M. STANLEY.

Order Assigning Cause for Hearing.

[Filed June 7, 1921.]

This cause is assigned for hearing at the ensuing October session. Two and one half hours will be allowed each side for oral argument.

Cause Argued and Submitted.

(October 10, 1921.—Before Knappen, Denison, and Donahue, C. JJ.)

This cause is argued by Mr. Frederick P. Fish, for the appellant and by Mr. Melville Church, for the appellee and is submitted to the Court.

Decree.

[Filed June 28, 1922.]

Appeal from the District Court of the United States for the Eastern District of Michigan.

This cause came on to be heard on the transcript of the record from the District Court of the United States for the Eastern District of Michigan, and was argued by counsel.

400 On Consideration Whereof, it is now here ordered, adjudged and decreed by this Court, that the decree of the said District Court, in this cause be and the same is hereby affirmed with costs.

Opinion.

[Filed July 3rd, 1922.]

401 Filed Jul. 3, 1922. Arthur B. Mussman, Clerk.

United States Circuit Court of Appeals, Sixth Circuit.

No. 3555.

THOMSON SPOT WELDER COMPANY, Appellant,

vs.

FORD MOTOR COMPANY, Appellee.

Appeal from the District Court of the United States for the Eastern District of Michigan.

Submitted October 10, 1921; Decided June 28, 1922.

Before Knappen, Denison, and Donahue, Circuit Judges.

KNAPPEN, *Circuit Judge:* Suit for infringement of United States patent No. 1,046,066, December 3, 1912, to Johann Harmatta, assignor to Thomson Electric Welding Company, which is the predecessor of plaintiff company. The invention relates to that branch of electric resistance-welding known as spot-welding, by which two sheets of metal are welded together in spots, as a substitute for riveting. Generally speaking, the welding is accomplished by the application of pressure and heating current, localized in spots on the opposite plane faces of the two metal sheets. Specifically, two pointed electrodes are applied to the opposite faces of the sheets, the electrode which feeds the electricity into the work and heats the metal to the welding point being caused to exert the pressure required to accomplish the weld. The specification states that "the necessary pressure may be exerted at the place of welding by the aid of any of those technical means which are suitable for producing or transmitting pressure, e. g., with a press either direct or by means
402 of indirect transmission by levers. Or it may be by means of simple hand levers, that is to say, by means of direct or indirect manual power, or by other means." The 21 claims of the patent relate some to the process, the others to the product.

Plaintiff relies on claims 3, 8, 12 and 17 as typical. They are printed in the margin.[1] The prominent defenses are anticipation, lack of invention, prior public use and estoppel. The district court

[1] "3. The herein described method of uniting two pieces of metal, consisting in pressing them together while passing a heating electric current from one to the other and localizing the flow of current and the heating throughout the operation in a spot or spots of circumscribed or limited area as compared with the area of the immediately opposed surfaces so as to limit the union of the pieces to a spot or spots.

found each of these defenses established and dismissed the bill. (268 Fed. 836.) Non-infringement is pleaded but not urged.

The patent has been adjudicated in but one other suit, viz., Thomson Electric Welding Co. (plaintiff's predecessor) v. Barney & Berry, in the First Circuit, decided in 1915. In that case Circuit Judge Dodge, who presided in the district court, held the patent void for lack of invention. The Circuit Court of Appeals held that the patent was not anticipated and that it involved invention, and reversed the judgment of the district court. The opinions of both the district court and of the circuit court of appeals are reported in 227 Fed. 428 et seq.

The art of electric resistance welding was old and far advanced in 1903, when the Harmatta patent was applied for. Professor Elihu Thomson, the head of plaintiff company and of its predecessor, was a pioneer in that art. In 1886 he obtained process and apparatus patents respectively (Nos. 347,140 and 347,141) for so-called butt-welding, which involved the uniting of the abutting ends of
403 metal wires, bars, etc., by applying heat at the joint and the adjacent surfaces by means of electrodes, and pressing the two pieces together when heated to welding temperature. There was here true resistance welding, with pressure of the parts involved, although the electrode did not exert the welding pressure. In 1889 Thomson obtained a patent (No. 396,015) for electric riveting, which involved the heating of the rivet when in place by means of a current passed through it by the use of electrodes, under pressure thereon, the effect being not only to swage the rivet and weld it to the adjoining metal, but apparently (when desired) to weld together, in part at least, the portions of the plates immediately adjoining the rivet.

In 1891 Thomson obtained a patent (No. 444,928) for what is called lap-welding. While the specification states that the invention is specially adapted to the welding of the overlapped edges of

---

"8. The method of electrically welding two plates or sheets of metal together face to face between electrodes, consisting in restricting the area of contact of an electrode with said plates to a spot, passing a heating electric current from said electrode to the co-operating electrode through said spot to heat the work to welding temperature and applying pressure to the work in line with said spot to effect a welding of one plate to the other.

"12. The method of electrically welding two pieces of sheet metal to one another, consisting in pressing the sheets together by pressure applied and localized in a distinct well-defined joint or spot on the rear surface of a sheet while passing an electric current through them in the line of the pressure, thereby localizing the path of the heating current from one to the other of the meeting surfaces of the sheets to cause the said sheets to be heated to welding temperature by the electric resistance of the work at said spot, and applying pressure localized over said spot whereby the pieces are welded together at a distinct well-defined spot in their meeting surfaces answering the purpose of a rivet.

"17. Metal plates fastened together by a number of distinct or isolated welds on their meeting surfaces and in spots comprising meeting portions of the metal plates, the backs of said plates being practically unaltered in their metallic condition and the spots on the meeting surfaces being separated from one another by distinct unwelded areas."

plates, it is not so limited, but expressly includes "welding together strips, sheets, plates or bars of metal where it is desirable to form a joint of considerable length." According to the specification, "the surfaces to be welded are pressed together to form a union," the work being fed in the longitudinal direction of the joint "through suitable pressure devices [preferably roller electrodes], the work being properly arranged, so that the pressure devices will press the surfaces to be welded together and simultaneously passing the electric current through the work *at the point of pressure.*" The electrodes were employed to exert the welding pressure. The specification further states that "as the work is passed through such rolls with a continuous motion *each point,* as it comes between the rolls, is heated and the surfaces pressed together," etc. By way of further description of one of the figures it is said that "the electric current being now turned on as it passes from one roller to the other and across the point of pressure will heat the work to the welding temperature * * * after which the screw can be given a few more turns to effect a solid union. The work *having been thus started,* may now be moved along through or between the rolls so as to bring successive parts of the joint into position to be pressed and heated at the same time." [2]

In 1893 Thomson obtained a patent (No. 496,019) relating particularly to soldering sheet metal pieces flatwise, either by the use of solder or (when applied to tin-plates) by melting the tin
404 sufficiently to establish union thereby. The electrodes, in the form of clamps or otherwise, served not only to supply the necessary heat, but to exert sufficient pressure upon the overlapped sheets to effect their union. A roller electrode is disclosed, performing the double function of heating and pressing, and having its periphery corrugated or grooved. As stated in the specification—"The rollers exert pressure while the current heats the thin metal pieces at successive points between the rollers." This was, to say the least, electric-resistance spot-soldering.

In 1897 Robinson received a patent (No. 574,942) on so-called projection-welding, as specially applied to the welding of a splice-bar to the web of a railroad rail, the splice-bar having upon its inner face a number of projections which by the application of the heating current are fused, and by pressure made to form welds between the projections on the bar and the fused opposing portions of the rail. Kleinschmidt, in 1898, took out a patent (No. 616,436) for a similar process, and by methods not essentially unlike those of Robinson.

Whether or not the Thomson so-called lap-welding invention should be regarded as an absolute anticipation of the Harmatta patent, we think the state of the art to which we have referred left no room for invention in Harmatta. Thomson's lap-welding patent is criticized as not plane-face welding, much less spot-welding. We see no distinction upon principle between plane-face welding and lap-welding; the former certainly embraces the latter. If Thomson's roller electrode device was capable of welding a line or seam

[2] All italics in this opinion are ours.

in a metal lap-joint, it was readily adaptable to line-welding together coterminous plane-face plates. Harmatta's original application made in ignorance of Thomson) disclosed roller electrodes broadly enough to include that very use. We think Thomson's lap-welding invention was in essence a welding in points. In fact, his line seam was merely a succession of adjoining points. The specification repeatedly speaks of the "point of pressure," says that "each point as it comes between the rolls is heated," etc.; "the current passes across the point of pressure." It satisfactorily appears that although Thomson's roller electrodes in the form shown in the patent, were not practicably adapted to commercial spot-welding as disclosed by the Harmatta patent, they could readily be made to do such spot-welding by the use of suitable projections upon the face of the rolls (Thomson later did spot-soldering by the use of such projections); and assuming that pin electrodes were essential
405 to successful commercial spot-welding, that form of electrodes was old, as illustrated by Thomson's electric soldering patent referred to. In our opinion the art of soldering is analogous to that of welding. The difference in degree of heat generated by the electric resistance, as required in welding and soldering respectively, is not sufficient to defeat analogy. By the use of enough more heat Thomson's soldering device could readily have effected spot-welding. Such analogy seems recognized in the Benardos patent, whose invention is applied "to welding thin metal sheets and rods, and the soldering of metals as well as their hardening and annealing"; and in the Lemp patent (No. 553,932) issued to plaintiff's predecessor, which provides for "welding, soldering, cementing, or similar operations." No essential difference in principle between heating at points and heating in spots is apparent. Projection welding partakes, though not in so pronounced a sense, of the nature of spot-welding.

We agree with Judge Dodge that Harmatta's idea of "making his electric welds small in area rather than large in comparison with the areas of the opposed surface to be joined and isolating them so as to leave each surrounded by a comparatively large area of unwelded surface" does not involve invention in view of the prior art. In other words, given the desire for a welding in spots, naturally enough suggested by the prior art and by its commercial development, we think Harmatta's specific application of the principles of that prior art involved only the skill of the expert mechanic. Not only every principle, but every electric and mechanical process involved in the Harmatta claims was well-known in the prior or directly analogous arts, or in mechanical arts generally. We can not think in view of the prior art, that invention is to be found in the considerations, separately or collectively, that in Harmatta no bodily movement of the sheets is required, that the current is localized and pressure exerted solely by the electrodes, or by the difference in the form of the electrodes, or by the difference in amount of extruded metal, as compared with some of the earlier applications of resistance-welding. Although invention is not necessarily negatived by the fact that each element of the combination is old, the

question of fact whether the combination itself involves invention in view of the prior art is always present.

Our conclusion of non-invention, based upon a review of the prior art, is materially strengthened by the serious doubt whether Harmatta thought, when he filed his patent-application, that
406 he had patentably invented anything by the disclosure of spot welding, as a process or product distinct from point-welding or line-welding; as well as by the fact that others previous to the grant to Harmatta, and apparently in ignorance of Harmatta's claimed invention, successfully practiced the art of spot-welding. Harmatta's application was filed December 3, 1903. For "continuous welding," the specification disclosed roller electrodes for exerting pressure "whereby the advancing series of single points of the seam to be welded is united to a whole with a minimum amount of current." It also showed pin-shaped electrodes "which may be adapted to work on the smallest possible surface of contact," which could be used for the "welding of two metal sheets of equal thickness, intermittently or at certain spots only," and by the use of which, as illustrated, "a small round, very sharply defined place of welding is caused which perfectly answers the purposes of a rivet." But none of the claims contain in terms any reference to spot-welding. The first claim related to the process of electric welding "consisting in employing the electrodes not only to conduct the current to the objects being welded, but also to exert a regulable pressure on the same;" the second, to an apparatus for electric welding "comprising two electrodes between which the objects to be welded are introduced and means whereby one of the electrodes can be approached to and receded from the other;" the third, to an electrode apparatus for electric welding, comprising two roller electrodes between which the objects to be welded are introduced, and means for pressing the electrodes to the work"; the fourth, to an "electrode apparatus for electric welding, comprising two roller electrodes between which the objects to be welded are introduced, and means for rotating one or both of the rollers for the purpose of advancing the work in its path between the electrodes." Each of the four claims would literally read upon Thomson's lap-welding or roller-electrode device. The natural inference would be that Harmatta regarded the principle employed in roller-electrode and pin-electrode welding as the same. The patent office found nothing patentable in Harmatta's application until six years later. The patent issued nine years after the application was filed, and after numerous vicissitudes and amendments (including the entire elimination of the roller-electrode feature), and after the application had been placed in interference with the claims of Adolph Rietzel, to whom a patent had previously been issued on July 20,
407 1909; Rietzel's claims, as allowed, being adopted by Harmatta at the suggestion of the patent office for purposes of interference. Rietzel was the engineer, superintendent and general manager of plaintiff's predecessor. His application was filed February 24, 1905, and presumably in ignorance of Harmatta's application or claimed invention. From the beginning Rietzel's applica-

tion was owned by plaintiff's predecessor. The interference was declared in favor of Harmatta, for Rietzel's failure, as the junior party to the interference, to take testimony in support of his claim of priority-plaintiff's predecessor at the time owning both the Harmatta application and the Rietzel patent. What we have said is not intended as a criticism of plaintiff's predecessor or of counsel, or of the patent office. But the fact that the award of priority was not based upon an adjudication on the merits tends to weakens its force.

It, however, convincingly appears in the record before us that in 1898 (and about five years before Harmatta's application) Rietzel, while in the employ of plaintiff's predecessor, in several instances successfully joined two pieces of lapped metal at isolated spots by means of a Thomson butt-welding machine, the sheets of metal being united by pressing them together and at the same time passing the heating current from one electrode (or socalled contact) to the opposite electrode, at the selected spot on the meeting surface of the plates, the spots being restricted in area so as to leave well-defined and comparatively extensive areas of no-union completely surrounding the spots; one of the electrodes or contacts used being of standard size and form, the other being reduced by cutting down to a diameter of about $\frac{3}{8}$ of an inch.

Assuming, for the purposes at least of this opinion, the correctness of the contention that these spot-welds, while satisfactory and successful, were not considered by Rietzel a commercially practical experiment, and did not amount to a reduction to practice within the meaning of the patent law, or became an abandoned experiment, Rietzel's experience strongly discredits inventive quality in what Harmatta did several years later, including his disclosure of the use of pin-electrodes.

The fact also appears in this record that at various times, ranging from two years to five or six years before the issue of the Harmatta patent, and apparently in ignorance of his asserted invention, various manufacturers put out or used spot-welding machines with commercial success. Some of these uses antedated the issue of the
408 Rietzel patent. These experiences also tend to discredit invention in Harmatta.

It follows, in our opinion, from what has been said that the effect of the great commercial success of the Harmatta invention in the hands of plaintiff is entitled to little weight upon the question of invention, even were that question otherwise in doubt, which we think it is not.

Our conclusion of non-invention makes it unnecessary to consider the alleged McBerty prior use, the defense of equitable estoppel asserted against plaintiff, the standing of the De Ferranti patent, or any of the other defenses presented.

The decree of the district court is affirmed.

Denison, Circuit Judge, dissents.

409 United States Circuit Court of Appeals for the Sixth Circuit.

I, Arthur B. Mussman, Clerk of the United States Circuit Court of Appeals for the Sixth Circuit, do hereby certify that the foregoing (in five volumes) is a true and correct copy of the record and proceedings in the case of Thomson Spot Welder Company vs. Ford Motor Company, No. 3555, as the same remains upon the files and records of said United States Circuit Court of Appeals for the Sixth Circuit, and of the whole thereof.

In testimony whereof, I have hereunto subscribed my name, and affixed the seal of said Court, at the City of Cincinnati, Ohio, this 5th day of July, A. D. 1922. Arthur B. Mussman, Clerk of the United States Circuit Court of Appeals for the Sixth Circuit. [Seal of the United States Circuit Court of Appeals, Sixth Circuit.]

410 UNITED STATES OF AMERICA, *ss:*

[Seal of the Supreme Court of the United States.]

The President of the United States of America to the Honorable the Judges of the United States Circuit Court of Appeals for the Sixth Circuit, Greeting:

Being informed that there is now pending before you a suit in which Thomson Spot Welder Company is appellant, and Ford Motor Company is appellee, No. 3555, which suit was removed into the said Circuit Court of Appeals by virtue of an appeal from the District Court of the United States for the Eastern District of Michigan, and we, being willing for certain reasons that the said cause and the record and proceedings therein should be certified by the said Circuit Court of Appeals and removed into the Supreme Court of the
411 United States, do hereby command you that you send without delay to the said Supreme Court, as aforesaid, the record and proceedings in said cause, so that the said Supreme Court may act thereon as of right and according to law ought to be done.

Witness the Honorable William H. Taft, Chief Justice of the United States, the second day of December, in the year of our Lord one thousand nine hundred and twenty-two. Wm. R. Stansbury, Clerk of the Supreme Court of the United States.

United States Circuit Court of Appeals for the Sixth Circuit, ss.

I, Arthur B. Mussman, clerk of the United States Circuit Court of Appeals for the Sixth Circuit, do hereby certify that the transcript of the record of the proceedings of this court in the within entitled case heretofore certified by me for filing in the Supreme Court of the United States was correct and complete as the same then appeared in this Court.

In pursuance of the command of the foregoing writ of certiorari I now hereby certify that on the eighth day of December, A. D., 1922, there was filed in my office a stipulation in the above entitled case in the following words to wit:

412 No. 3555.

THOMSON SPOT WELDER COMPANY

vs.

FORD MOTOR COMPANY.

In the above entitled case it is stipulated that the record heretofore filed in the Supreme Court of the United States in support of the Petition for Certiorari may be taken as a return to the Writ of Certiorari. Thomson Spot Welder Company, by J. L. Stackpole, Its Attorney. Melville Church, Attorney for Respondent.

I further certify that the above is a true and correct copy of said stipulation and of the whole thereof. Witness my official seal, signature and the seal of said Circuit Court of Appeals at the City of Cincinnati, Ohio, in said Circuit this eleventh day of December, A. D. 1922. Arthur B. Mussman, Clerk U. S. Circuit Court of Appeals for the Sixth Circuit. [Seal of the United States Circuit Court of Appeals, Sixth Circuit.]

413 [Endorsed:] File No. 29,139. Supreme Court of the United States, October Term, 1922. No. 589. Thomson Spot Welder Company vs. Ford Motor Company. Writ of Certiorari. Filed Dec. 11, 1922. Arthur B. Mussman, Clerk.

414 [Endorsed:] File No. 29,139. Supreme Court U. S., October Term, 1922. Term No. 589. Thomson Spot Welder Company, Petitioner, vs. Ford Motor Company. Writ of certiorari and return. Filed Dec. 13, 1922.

SUPREME COURT OF THE UNITED STATES

OCTOBER TERM, 1922.

No. 589.

THOMSON SPOT WELDER COMPANY,
PLAINTIFF-PETITIONER,

v.

FORD MOTOR COMPANY, RESPONDENT.

BRIEF FOR PLAINTIFF-PETITIONER.

STATEMENT OF THE CASE.

This case is brought to this Court by writ of certiorari issued to the Court of Appeals for the Sixth Circuit.

The suit was brought by the plaintiff-petitioner alleging infringement by the respondent of Harmatta patent No. 1,046,066, for "Electric Welding" granted to the Thomson Electric Welding Company, December 3, 1912, on an application of Johann Harmatta filed December 3, 1903 (Vol. I, p. 387). There is no question as to plaintiff's title to the patent. The suit was brought in the United States District Court for the Eastern District of Michigan, Southern Division, which court (Killits, Judge) held the patent invalid, whereupon a final decree was entered dismissing the bill of complaint (Vol. I, p. 50).

Upon appeal to the Circuit Court of Appeals for the Sixth Circuit, that court, Circuit Judge Denison dissenting, affirmed the decree of the District Court dismissing

the bill upon the sole ground, as appears from the opinion by Circuit Judge Knappen (Vol. III, p. 2098), that in the opinion of a majority of the court the Harmatta patent was invalid for lack of invention and patentable quality. The majority of the court expressly refused to consider any other defenses than want of patentability. His Honor Judge Denison, by dissenting from the conclusion of the court, must have regarded all the other defenses, as well as that of want of patentable quality, as insufficient.

The decision of the Circuit Court of Appeals for the Sixth Circuit, here sought to be reviewed, is in conflict with a previous decision of the Circuit Court of Appeals for the First Circuit in the case of *Thomson Electric Welding Company et al.* v. *Barney & Berry, Inc.*, October 5, 1915, holding the same Harmatta patent valid and infringed (Vol. I, p. 4), 227 Fed. Rep. 428.

The single and exact issue upon which the case was decided in the Sixth Circuit adversely to the patent was on full hearing decided by the Court of Appeals for the First Circuit in favor of the patent. In each case the full state of the art was presented and in each case there was no doubt that the defendant infringed.

The invention of the Harmatta patent resulted in the production of welds, integrally uniting thin sheets of iron or steel in spots, such welds taking the place of rivets, riveting being the only method for uniting such sheets which was in use prior to the Harmatta invention. *The process and product*, whether patentable or not, *were absolutely new* with Harmatta. By the invention, for the first time it was possible to unite by an integral union and without rivets or solder, plane flat sheets of metal, laid one upon the other, at as many spots, located anywhere in their meeting faces, as might be desired.

No one, before Harmatta, had ever united two plane

sheets in this manner by any method of welding, electric or blacksmith.*

Professor Wagner, professor of mechanical and electrical engineering at Rose Polytechnic Institute at Terre Haute, Indiana, has testified without contradiction that

> "Harmatta struck out in a new field and accomplished something which had never before been accomplished by any method, namely, the welding together at isolated spots, and without previous preparation, parallel, superimposed metal sheets." (Vol. I, p. 343).

The patented process is applied to a greater extent each year wherever sheets are to be united, for example, in steel boxes, cases, tubes, the steel finish of buildings and railway cars, automobile bodies, cooking utensils, stoves, furniture and innumerable articles made of thin sheets of iron or steel (Vol. I, p. 62).

The petitioner has made and leased or sold to users in all parts of the United States upwards of 1,000 machines on which the Harmatta process of spot welding is carried out (see Pl. Ex. No. 11, "List of Licensed Spot Welder Machines"). Upwards of 2½ billion spot welds are made on these machines every year (Vol. I, p. 134).

The defendant, a large manufacturing concern, has infringed the Harmatta patent by practicing the process and producing the product of said patent without license. There is no question of infringement in this case.

*Lap welding of the edges of two sheets, as in the well known case of welding the lapped edges of pipes was known, but this, as we shall show, is in no sense spot welding.

THE ISSUE AND THE DEFENSES.

The sole issue is whether the Harmatta patent in suit is valid. That it has been infringed by the defendant has never been questioned in the lower courts and we assume that it will not be questioned here.

The validity of the patent is attacked on the following grounds:

1. That the subject-matter of the Harmatta patent is lacking in patentable quality as compared with the prior patented art. It is not contended that there is any single patent in the prior art which discloses Harmatta's invention. Whether these prior patents taken as a whole disclose or suggest processes which are so analogous to Harmatta's patented invention that the man skilled in the art would without the exercise of invention practice the Harmatta process and produce the Harmatta product is the main question in this case. We shall therefore discuss this defense first.

2. That the Harmatta patent was not legally issued in view of the Patent Office proceedings. This defense ignores the controlling fact that Harmatta's original application, filed December 3, 1903, fully disclosed every detail of the process and every characteristic of the articles described and claimed in the issued patent.

3. An alleged prior use by a man named McBerty. As we shall show, even on the admitted facts this defense is not substantiated. McBerty's use was at most a mere abandoned experiment. Further, as we shall show, the established facts contradict the possibility of any prior use by McBerty.

4. That the plaintiff is estopped to deny that a man named Rietzel was the first and original inventor of the subject-matter of Harmatta's patent. This defense is based on a mistaken view both of the facts and of settled

principles of law as we shall show. To us it is unintelligible.

5. That a man named DeFerranti was the original and first inventor of the subject-matter of Harmatta's patent. We shall show that there is no basis for this defense. It seems impossible that it should be argued by defendant.

figure marked "Pressing", whereby the plastic metal at the joint of the two articles to be welded is united into a weld which is a molecular union of the metal itself.

The current employed in electric welding is heavy, that is of high amperage, but of low pressure, that is of low voltage. It therefore requires conductors of low resistance in order to carry the current to the work. Copper conductors of large cross-section are therefore used in electric welding. When this heavy current is forced through parts which are of high resistance compared with the conductors it generates heat. If the current is heavy enough and the resistance is large enough the parts will be raised to a welding temperature, about 2400° F. One of the essential steps in electric welding is to force this heavy current carried by large copper conductors through the work under such conditions that the resistance of the work causes a welding heat to be developed.

In the Thomson welding process, in the form shown in his fundamental patents, the iron or steel pieces to be welded extending out from the copper electrodes are not only of greater specific resistance than the electrodes (iron and steel are much poorer conductors than copper), but they are of substantially *decreased cross-section*. They therefore offer great resistance to the passage of the welding current, which resistance is increased to some degree by the imperfect contact at the joint.

In the specific application of his underlying invention which Thomson described and illustrates in his original patents the cross-sectional area of the work at the welding point is made comparatively small so as to confine or concentrate the heavy current to a small cross-sectional path, the resistance of which causes the current to generate the welding heat at that point. This is in accordance with the well known electrical law that the resistance of a conductor increases with the decrease of its cross-

section, or as more commonly stated its resistance is inversely proportional to its cross-section.

As we shall show, every inventor in the art of electric welding before Harmatta developed his particular electric welding process on this principle and law, namely to provide *in the work itself* a restricted path of comparatively small cross-section and hence high resistance through which he forced the heavy welding current for the purpose of generating the welding heat.* Harmatta, as we shall show, in the process of the patent in suit departed diametrically from this method of handling an electric current and discovered a new method of concentrating the current which was in seeming contradiction to established electric laws (*infra*, p. 16).

The generic Thomson electric welding process had gone into wide commercial use as early as 1887, sixteen years prior to Harmatta's invention. It was employed mainly for "butt welding", as welding the abutting ends of two rods is called. It was used also for welding other pieces of metal together at the places at which they were held in contact, as described in several patents of the art prior to Harmatta, which we shall explain, but before Harmatta it was never used for welding two sheets of metal in spots where the weld performs the duty of a rivet or in any way foreshadowing the Harmatta invention.

The only way of securely uniting sheets of metal at any point in their contacting surfaces, known in the art before Harmatta, was by rivets. Soldering only stuck them together. Riveting involved making holes in the two sheets, thus weakening them, and inserting and heading the rivet. The finished article was made up of three separate things, namely, the two sheets and the rivet

*The Court will note that such is the principle of the later Rietzel patent discussed (*infra*, pp. 69 and 219).

with its two projecting heads. The Harmatta process of electric spot welding is vastly superior to the old riveting process and has largely superseded it as a method for uniting sheets of metal. When a weld is made by the process of the Harmatta patent it results in a strong and perfect union; no holes are made, the metal is continuous from one sheet to the other through the weld and the backs of the sheets are flat with no unsightly and objectionable projections such as rivet heads.

Harmatta's idea of welding two such plane sheets at any spot in their meeting surfaces was a new departure not only in electric welding but in welding by any method (Vol. I, p. 343).

Harmatta was the first to make an invention whereby two plane sheets of metal could as a matter of practical commercial business be united at any spot in their meeting surfaces otherwise than by rivets, bolts or solder.

THE PATENTABLE QUALITY OF HARMATTA'S INVENTION.

The reasons why Harmatta's process and product were patentable are:—

1. Harmatta produced a new result, namely a small round *weld* (a spot weld) uniting two plane sheets of metal at any place in their meeting faces. This was radically new.

The idea of such a weld was in itself a flash of inventive genius. No one had ever before thought of making such a weld, either by blacksmith welding or by electric welding. It was as radical an idea as that of putting the eye in the point of a sewing machine needle, Howe's invention that made machine-sewing possible, and as the constant contact of electrodes in a telephone transmitter, the so-called microphone, which is the basis of the success of telephony.

No case decided by this Court has ever denied patent-

ability to an invention, be it process, product or machine, which was based on such a radically new idea and which accomplished such a definitely new and valuable result.

2. To make this spot weld Harmatta manipulated the articles with which he dealt, namely the sheets, *in a new way* by indiscriminately superimposing one upon the other and he made his electrodes perform a function, which no electrodes, used in electric welding, had ever before performed.

3. In so doing he carried out *a new technical process*, that is, the electric current, which generates the welding heat, behaved and operated in an entirely new way, which was unexpected and indeed contrary to the teaching and experience of the prior art, and he applied the welding pressure to a condition, which seemed to make such application impossible.

THE HARMATTA INVENTION.

As shown in Fig. 1 of the patent (Vol. I, p. 387), Harmatta places the two sheets of metal, in practice generally not over an eighth of an inch thick, with their plane surfaces in contact, between two electrodes *a*, *b*, which have bodies of relatively large cross-section, but tapered ends, which bear upon the work with comparatively small facial area. Right here are two novel features in electric welding:—

First, although the overlap of the sheets is shown in Fig. 1 as small, *the sheets may be overlapped to any extent* as no feature of the process is affected in any way by the extent of the overlap of the sheets. This, as we shall show, is radically different from each and every process of the prior art in which the limited overlap of the contact area of the parts to be welded is an inherent and necessary characteristic of such old process in confining the current to the parts where the weld is made.

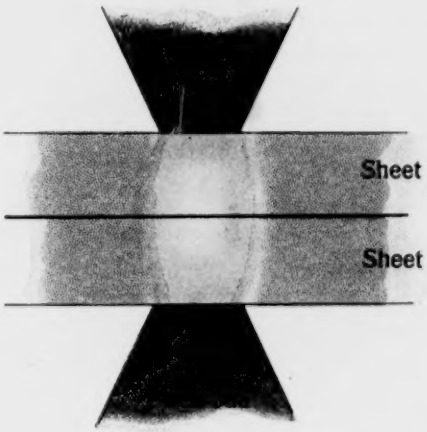
Second, Harmatta, by tapering the ends of his electrodes, for the first time in the art confined to a small definite path, that is "concentrated" or "localized" the welding current *solely by means of the electrodes* and without assistance from the arrangement or shape of the articles being welded, the size and contour of the weld being determined by the shape of the electrodes. Harmatta's electrodes, as we shall show, differed not only in shape but *also in function* from any electrodes of the prior art for in no process of the prior art was the current concentrated solely by the electrodes but was concentrated by the limited area of contact of the parts to be welded.

It was radically new in the welding art to place two metal sheets in indiscriminate facial contact over an area, the extent of which was immaterial, and to apply pointed electrodes to the opposite sides of those sheets to concentrate the current. No prior inventor had ever suggested doing this. This was a radically *new principle of operation* inherent in and necessary to Harmatta's invention.

This new principle of operation alone, because it dispenses with the necessity of a particular arrangement or shape of the articles being welded, has given his process great flexibility and adaptability to the welding of all kinds of thin metal articles.

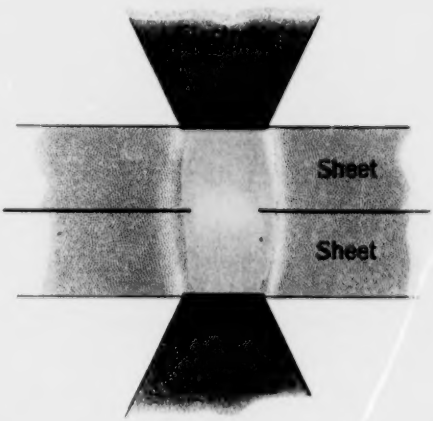
With the work to be welded placed in position, Harmatta first grips the sheets between the electrodes, one electrode being on one side and the other on the other side of the spot to be welded, and at the same time passes an electric welding current from one electrode to the other through the work.

Harmatta *discovered* that under such conditions the current would not spread itself in the sheets and cross the joint between them over their wide area of contact, but that it would flow across the joint between the sheets



only at the path or spot in line with the ends of the electrodes. The resistance of this joint and of the metal of the sheets at the spot at which the current is concentrated, heats the sheets at this spot, and at this spot only, to a welding temperature as shown in the upper figure of the accompanying drawing in which the metal heated to welding temperature is shown in yellow, the less heated metal in red and the cold metal in blue.

The discovery that the current would thus be "concentrated" by the pointed electrodes and would confine itself to the path or "spot" between the ends of the electrodes was radical. This was a discovery of *a new function* to be performed by electrodes. There is no suggestion of any such phenomenon in the prior patents, as we shall show. In accordance with all known laws of electricity the resistance of a conductor, here the sheets, is inversely proportional to its cross-section, hence it would be expected that the resistance at the joint between the sheets, which is of any area however large, would be too small to create the heat necessary for welding. But contrary to such expectation Harmatta discovered that the heavy (high amperage) welding current of low voltage would not so spread itself but would stay in the direct path and cross the joint between the tapered ends of the two electrodes. Nothing of that sort was suggested or fore-shadowed by any item of the prior art. It was indeed contrary to the teaching of the prior art and a discovery of rare quality. It is the kind of "discovery" that is intended to be protected by the patent statutes and constitutes a real invention.



Harmatta then presses the electrodes toward one another as shown in the lower figure of the accompanying drawing. He is able to do this in spite of the already existing extended bodily contact of the sheets and their consequent relative immobility, because *the small ends of the electrodes bear upon softened metal only.* This was a

HARMATTA.

HEATING.

PRESSING.

radically new feature in electric welding; in each and every welding process of the prior art the parts to be welded are in contact over a limited area and as those parts become soft the pressure of the electrodes, which also bear upon cold unyielding metal, one at each side of those parts, squeezes the parts *bodily* together to make the weld. No such bodily movement of the sheets is possible or is carried out in the Harmatta process in which the sheets are in extended facial contact and therefore can not be moved bodily any closer together.

The movement of Harmatta's electrodes is only very slight. There is only a very slight indentation on the backs of the sheets on which the electrodes bear. This is a novel characteristic peculiar to the Harmatta process. No one before had ever made a weld with so little movement of the electrodes and disturbance of the metal. There is little or no extruded metal in a true Harmatta weld. The reason is that when Harmatta's electrodes apply pressure there is no place for the metal to go because the soft metal is surrounded as by a frame of cold unyielding metal, and therefore but a slight compression of the electrodes serves to force the hot metal together at the spot between the sheets to make a real weld just at that point and at that point only.

In every prior welding process the softened contacting parts are squashed together by the electrodes and the extruded metal squeezes out on each side of the joint. No such operation is possible or is carried out in making an Harmatta spot weld.

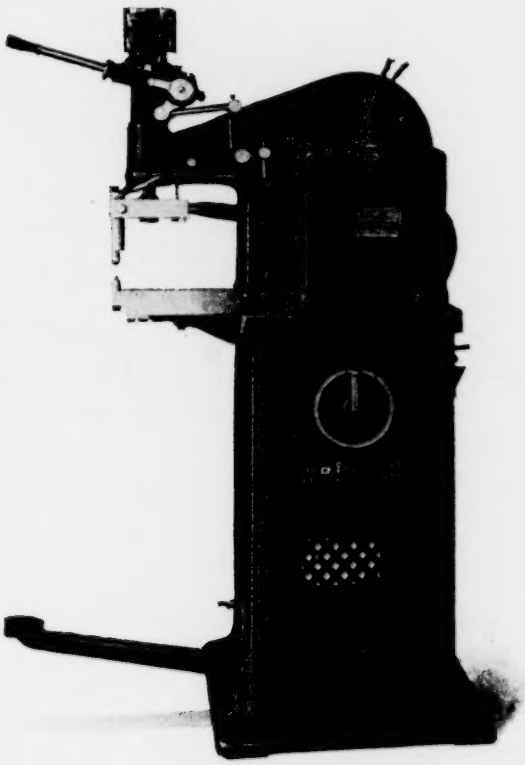
There is no suggestion in any patent of the prior art of such a small pressing movement of the electrodes or of the result accomplished, namely a small weld surrounded with cold metal and with only the slightest indentation on the backs of the sheets where the weld is made.

For the first time in the art of welding in general,

Harmatta welded together two plane sheets of metal at an isolated spot in their meeting faces.

For the first time in the art Harmatta produced a process by which metal sheets as a whole were united *in situ*, a weld being made without moving one sheet bodily toward the other. Only slight indentations in the backs of the sheets are made by the pressure of the electrodes on the softened metal.

The spot welding process of the Harmatta patent was first introduced into the United States in 1904, directly from Harmatta, by the purchase of a license for kitchenware and like articles by the National Enameling & Stamping Company, well known to be then and now the largest manufacturer of kitchenware in the United States, from the Essenhutte Silesia Company of Hungary, the owner of Harmatta's rights. The license, dated December 3, 1904, is in evidence (Vol. I, p. 433). With the license the National Company purchased two Harmatta spot welding machines which are now in its factory and have been in constant use up to the present time. Since then the National Company has built and used between eighty and one hundred spot welding machines (Vol. I, p. 125). Undoubtedly this extensive use of the Harmatta process and the sale of its products by the National Company beginning in 1904 spread the knowledge of Harmatta spot welding throughout the United States.



A TYPICAL SPOT WELDING MACHINE.

We show here Plaintiff's Exhibit No. 1, a picture of a spot welding machine used by the defendant. It is a typical spot welding machine.

In operating the machine the workman places the two sheets of metal face to face between the electrodes, which are shown extending from horizontal arms at the left of the machine and with their ends slightly separated from

PLAINTIFF'S EXHIBIT No. 1.

Defendant's Spot Welder.

one another. The sheets rest upon the lower electrode. He thereby locates the spot to be welded *at any desired point* in the plane meeting faces of the sheets (a possibility never attained by any one or by any process before Harmatta).

The operator then, either by the foot treadle or by the upper hand lever, presses the upper electrode down toward the lower electrode until the two sheets are held firmly between the electrodes at the spot to be welded. He turns on the current by a suitable switch and when the parts have been sufficiently headed he gives the electrodes an extra squeeze to complete the weld. He then cuts off the current and releases the work.

The operation is simple but requires a certain amount of skill, easily acquired by the operator, in turning off the current at the right moment and in operating the pressure devices.

THE NOVEL TECHNIQUE OF HARMATTA'S PROCESS.

As already stated, Harmatta's invention is radically new from at least three aspects.

First, the original *idea* of making a weld to take the place of a rivet at any place in the meeting faces of the plane sheets of metal.

Second, the idea of a new manipulation of the parts and elements involved, namely the indiscriminate placing of the two plane sheets face to face without regard to the place or to the extent of contact, and the use of pointed electrodes instead of the arrangement of the work itself to concentrate the current, and

Third, the discovery and invention of a new welding technique.

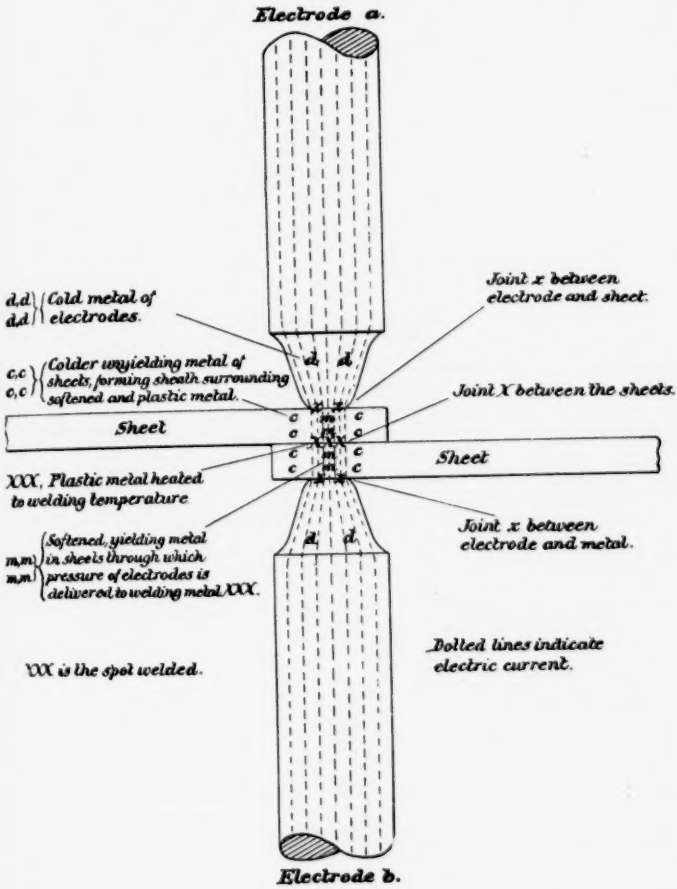
The First and Second above stated propositions need only to be stated to be understood and appreciated. The Third we will explain more fully.

In the accompanying drawing we have illustrated the

phenomena which take place in the Harmatta process of spot welding described by plaintiff's expert Gravell (Vol. I, pp. 61-63). In this drawing the size of the parts is exaggerated for purposes of illustration. The parts are shown in cross-section.

The electrodes *a*, *b* are pointed and press with their ends opposite to one another against the backs of the sheets which lie in facial contact.

The current, illustrated in dotted lines, is concentrated or localized in a narrow path through the sheets by the points of the electrodes.



The surprising thing is that the resistance to the flow of the current in this path caused by the metal of the sheets does not cause the current to spread out in the sheets, and thereby take a wide path of less resistance. The resistance of these parts generates heat and, as the resistance is greatest at the joint, the greatest heat is there generated (Gravell, Vol. I, p. 85; Thomson, Vol. I, p. 540, Q. 59). As the resistance of the metal increases and its temperature rises another surprising thing is that this increase in resistance at the spot does not itself force the current to spread into the surrounding cold metal of less resistance, and thereby prevent the metal at the spot from ever reaching the high temperature necessary for welding.

Heat flows from the heated parts into the cold surrounding metal.

The metal in the sheets at the joint X, X, X between the sheets is soon raised to a welding temperature at which it becomes plastic and weldable.

The heat generated at the joints *x*, *x* is dissipated through the sheets and through the masses *d*, *d* of the cold electrodes so that the metal of the sheets near these joints does not rise to welding temperature but does rise to a high enough temperature to become somewhat soft and yielding. (If it rose to too high a temperature the electrodes

TECHNIQUE OF HARMATTA PROCESS.

and the sheets might become so soft as to prevent the transmission of the pressure of the electrodes to the metal at the joint X, X, X to be welded or the electrodes might even be welded to the sheets, or punch holes through them.)

The heat generated in the parts *m*, *m* between each electrode and the joint X, X, X and the heat flowing into those parts raise them also to a temperature at which they become soft and yielding.

The surrounding metal *c*, *c*, *c*, *c* in the sheets is of course heated by the flow of heat into it but not high enough to soften it or make it yielding. It is, as compared with the enclosed metal *m*, *m*, X, X, X and *m*, *m*, cold and unyielding.

The Harmatta process, therefore, creates this condition, namely plastic metal at the joint X, X, X heated to welding temperature at a spot at the joint between the sheets, which plastic metal is backed by soft yielding metal *m*, *m*, *m*, *m*, and all the softened metal is surrounded by comparatively cold unyielding metal, *c*, *c*, *c*, *c*. *This condition, for the first time created in the art by Harmatta, makes it possible to weld the metal together at the joint X, X, X without moving the sheets bodily towards one another.* No weld had ever been made before without moving the welded articles bodily towards or into one another.

In the Harmatta process the pressure of the electrodes is transmitted to the plastic metal at the joint X, X, X between the sheets by squeezing down firmly but slightly the soft metal *m*, *m*, *m*, *m*, back of the plastic metal, and as the unyielding surrounding cold metal *c*, *c*, *c*, *c* prevents any sidewise movement or escape of the soft and plastic metal in the two sheets, the plastic metal at the joint X, X, X of the two sheets is forced together to make the weld. The weld has substantially the same area as the ends of the electrodes.

This operation of pressing and moving only softened yielding metal by localizing the pressure thereon, without moving bodily the articles being welded, was absolutely new with Harmatta.

To state the matter more briefly:

In the Harmatta process an electric current is concentrated or localized solely by tapered electrodes in those portions of contacting metal sheets which lie between the electrodes. The resistance met by the current does not spread the current throughout the sheets but causes the metal adjacent to the joint X, X, X, between the sheets to heat to welding temperature and become plastic in spite of the dissipation of heat through the surrounding cold metal *c*, *c*, *c*, *c* of the sheets. At the same time the parts *m*, *m*, *m*, *m* of the metal sheets, lying between the metal at the joint X, X, X heated to welding temperature and the ends *x*, *x* of the electrodes, are heated enough to be soft and yielding. The pressure exerted by the electrodes acts only upon the yielding and plastic metal lying between the ends of the electrodes, all of which metal is confined in a comparatively cold unyielding metal sheath *c*, *c*, *c*, *c*, and thereby completes the weld without moving the sheets bodily towards one another.

A slight indication on the backs of the sheets shows the effect of the pressure of the electrodes on the softened metal.

PATENTABLE NOVELTY OF HARMATTA'S INVENTION BRIEFLY STATED.

Our discussion of the prior art will show, we submit, that from any one of three points of view there was patentable novelty in Harmatta's invention:—

1. *The idea of making a spot weld, i. e.*, a weld uniting two thin plane sheets of metal at any place or at any number of places in their meeting faces, which perfectly answers the purpose of a rivet.

2. *The idea of a new manipulation*, namely (*a*), placing those sheets in any kind of facial contact, without regard to the extent of that contact, and (*b*), using pointed electrodes to bear upon the work. This involved *the new idea of a new functional operation of the electrodes*, namely that of being the sole means of concentrating the current. In all previous electric welding it was the predetermined relative arrangement or shape of the two pieces to be welded which confined the current to a path of limited cross-sectional area, by which the resistance necessary for the generation of the welding heat was provided.

3. *The technique of the process*, as above explained, involving a new and unexpected behavior of the current and a new pressing effect produced under new conditions.

Harmatta's invention therefore involved *a new result*, the spot weld, *a new manipulation* of the parts to be welded, *a new function* of the welding instrumentalities and *a new technique* in the welding steps of heating and pressing.

PATENTS OF THE PRIOR ART.

The patents of the prior art relied on by the defendant to show lack of patentable novelty in Harmatta's invention, may be divided broadly into two classes: *first* those which describe processes and devices which are *not* electric welding, using that term in the sense of the art created by Prof. Thomson's basic patents of 1886, and *second* the patents which relate to electric welding (Gravell, Vol. I, p. 151).

The patents which are *not* for electric welding are as follows:

Benardos, No. 363,320 for arc welding.

Coffin, No. 437,571 and Benardos German patent No. 50,909 for hot resistor welding.

Thomson, No. 496,019 for soldering.

Blanchard, No. 466,266, Lemp 531,197 and Burton 647,694 for heating only.

Thomson, No. 396,015 for riveting.

All of these patents were set up in the answer and those of them which were considered at all pertinent were discussed in the Record in the Barney & Berry case in the First Circuit.

The patents on *electric welding* besides Thomson Nos. 347,140, 347,141, already discussed (*supra*, pp. 6–8), are as follows:—

Robinson 574,942 and Kleinschmidt 616,436 for butt-welding;

Thomson 444,928 and Lemp 553,923 for lap joint roller welding.

Perry 670,808 for cross-wire welding, and

Parkinson (British) 14,536 of 1894 for glut-welding.

All of these patents, with the exception of Robinson and Parkinson, were set up in the answer and referred to in the Record, as far as deemed pertinent, in the Barney & Berry case in the First Circuit.

The Robinson and Parkinson patents add nothing material to the prior art disclosed by the other patents.

The Harmatta patent itself refers to the butt-welding process (Thomson No. 347,140, and No. 347,141) the lap-joint roller welding process (Thomson No. 444,928, and Lemp No. 553,923), arc-welding (Bernardos No. 363,320) and hot resistor welding in which the heat is developed in resistance material and is imparted to the work by conduction (Coffin No. 437,571 and Benardos German patent No. 50,909). It specifically disclaims the method set forth in the Kleinschmidt patent No. 616,436, which is a species of butt welding.

The Patent Office allowed Harmatta's patent after due consideration of the Benardos United States patent, Thomson patents Nos. 444,928 and 496,019, the Klein-

schmidt patent, the Burton patent, the Perry patent and others not above referred to.

Not one of the foregoing patents suggests the idea of welding together at any point in their contacting surfaces two plane thin sheets of metal or of any way of manipulating the pieces to be welded or the welding instrumentalities so as to carry out that idea.

It is not contended, as we understand the defendant's position, that any single patent of the prior art anticipates Harmatta's invention (Dyer, Vol. I, p. 592, X-Q. 110), but the defendant's argument is that although Harmatta's spot welding was in fact absolutely new with him, the state of the art was such that no invention was required, and that a man skilled in the art needed no aid of an inventor to give the world this extraordinarily important and far reaching improvement in electric welding which takes the place of riveting in sheet metal work.

The best answer to this contention is the plain fact that no one prior to the date of Harmatta's application did practice that invention, large and important as was the field open for it. (The abandoned experiments of Rietzel and the alleged prior use by McBerty have, as we shall show, no anticipatory effect whatsoever.)

The facts established by this record are that in 1886 Thomson invented electric welding as disclosed in his patents No. 347,140 and No. 347,141. Thereafter this brilliant inventor, and others exercised their ingenuity and invention in efforts to apply the broad process of electric welding to many kinds of articles and to many arrangements of articles, but they all followed the specific application of electric welding which Thomson had invented in 1886, namely *butt welding* and variants thereof, and not one of them suggested the idea or solved the problem, or even attempted to solve the problem, of uniting by electric welding two plane sheets of metal at any point or

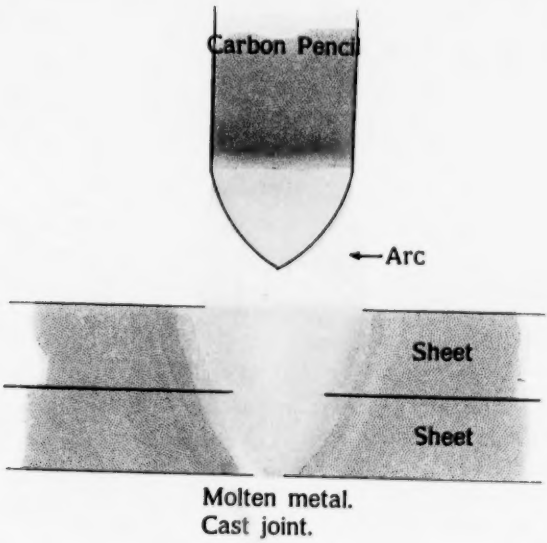
spot however remote from their edges, thereby obtaining a practical substitute for a rivet.

Harmatta was the first to solve this problem, which he did by *the process of the patent in suit which has methods of operation which are the antitheses of those of the processes prior to his invention.*

Harmatta's invention was based on the broadly novel idea of welding together two thin *plane* sheets of metal *at any spot* in their meeting faces. No one had ever before thought of doing that by any method.

Harmatta's invention marked an epoch in the art of electric *welding* and opened the tremendously wide and valuable field of uniting by electric welds two sheets of metal *at any point* in their contacting surfaces. The process has gone into the widest possible use in the manufacture of all kinds of sheet metal articles. The defendant has used it and cannot deny its utility.

Under these circumstances it would seem hardly credible that the practice of the Harmatta process was, prior to his date of invention so far suggested by the patents and practice of the prior art that the man skilled in the art without the exercise of invention would be naturally led to practice this new and immensely valuable process. He certainly did not do so.



The undisputed facts therefore indicate most emphatically that Harmatta made a real invention, a real advance in the art of electric welding which was patentable under the laws of the United States.

The Court of Appeals for the First Circuit, appreciating these facts, has found that the Harmatta patent is valid. Vol. I, p. 4. We confidently submit that this Court will see no reason to depart from the conclusion reached by that Court of Appeals although a majority of the Court of Appeals for the Sixth Circuit took the opposite view in this case.

BERNARDOS No. 363,320.

HEATING BY ELECTRIC ARC.

NO PRESSING.

Molten metal.
Cast joint.

BENARDOS PATENT No. 363,320, MAY 17, 1887
(Vol. II, p. 1030).

This patent does not describe electric welding (Gravell, Vol. I, p. 151). It describes *an electric arc process of melting metals*, which can be used for melting together parts of two metal plates. As shown in Fig. 2, one of the terminals of an electric circuit is connected to the plate r, which lies upon the plate r^1. The other terminal is connected to a carbon pencil D. The patent states (p. 1, lines 87-93):—

> "When the carbon D, under these conditions, is brought into proximity to the metal to be operated on, the voltaic arc will be produced between the two, with the effect of heating, softening, and finally *melting* the metal at the point where the arc meets it."

That is, the metal is melted from the back of the superimposed plate down through the two plates until the metal runs together and a cast metal joint is made. The same effect could be produced by an ordinary blow-pipe or plumber's torch acting upon the back of the sheets of metal laid together. *The metals are not welded*, because they are melted and there is no pressure applied to the sheets in contact. Welding requires pressure as well as heat. Pressure is an essential characteristic of the Harmatta process. These melting or fusing processes are not welding.

No one would ever think of trying to attach two sheets of metal together on their faces by this electric arc process, because the metal is necessarily melted, whereby the quality of the metal is destroyed and a hole is or may be made, and the backs or outside surfaces of the sheets are damaged and roughened by the flowing of the metal. The Benardos process begins by heating on the back surface of

one of the sheets. The characteristic of electric welding is the opposite, namely, that the heating is in the metal itself at the joint between the sheets.

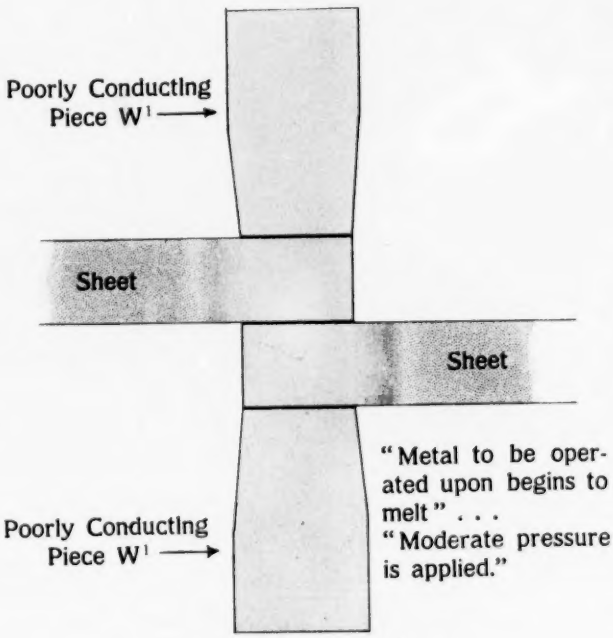
In the accompanying drawing we have illustrated the electric arc process of Benardos. The arc between the pencil electrode and the metal sheet is of very high temperature and melts that portion of the sheet adjacent to it. The high heat is indicated by the yellow.

This Benardos patent, therefore, bears no resemblance whatever to the Harmatta process or product. The Benardos process is disclaimed in the Harmatta patent as follows (p. 1, lines 64-69):—

> "I disclaim those processes of fastening pieces of metal together in which the parts are heated and practically melted down by an electric arc generated on the back of the piece by 'drawing' an arc by means of the electrode."

GERMAN PATENT TO BENARDOS No. 50,909, OF 1890 (Drawings Vol. II, p. 1151, Translation, Vol. I, p. 423).

Following the quotation just made from the Harmatta patent, Harmatta continues and says that he also disclaims (p. 1, line 70)—



> "other processes in which the welding heat is generated externally and electrically in a resistance material and is imparted to the work by heat conduction from said resistance material in contact with the work."

This is the process of the German patent to Benardos of 1890 (Gravell, Vol. I, p. 155).

Fig. 1 of this patent is typical. It shows one terminal of an electric circuit at the plate A^1, which is superimposed upon the plate A, the edges of the plates overlapping. The other terminal is connected by a suitable handle to a piece of resistance material *w*, which is described in the patent

BERNARDOS GERMAN No. 50.909 — 1889.

HOT RESISTOR HEATING.

A cast joint is made.
Solder may be used.

as "a small piece *w* of fire resisting, poorly conductive material". This handle and the piece *w* constitute a "soldering iron". When the current is turned on, the conductor *w* "soon begins to glow".

The process is described in the patent (Vol. I, p. 424, lines 10-17):—

> "By cutting resistance out of the circuit with the aid of a rheostat C, Fig. 1, *the temperature of the piece w is raised until the metal to be operated upon begins to melt.* Then, while moderate pressure is applied, either the electric soldering iron is moved along the seam to be produced, or else the metal piece to be operated upon is moved along under the stationary soldering iron. When the operation has been completed, the current is interrupted by a switch and then the soldering iron is removed from the metal."

The process of this German Benardos patent is not electric welding, but is fusing by electric heating, and differs from the United States Benardos patent No. 363,320, above discussed, in applying the heat by means of highly heated resistance pieces *w* applied to the backs of the metal sheets to be fastened together instead of by means of an electric arc.

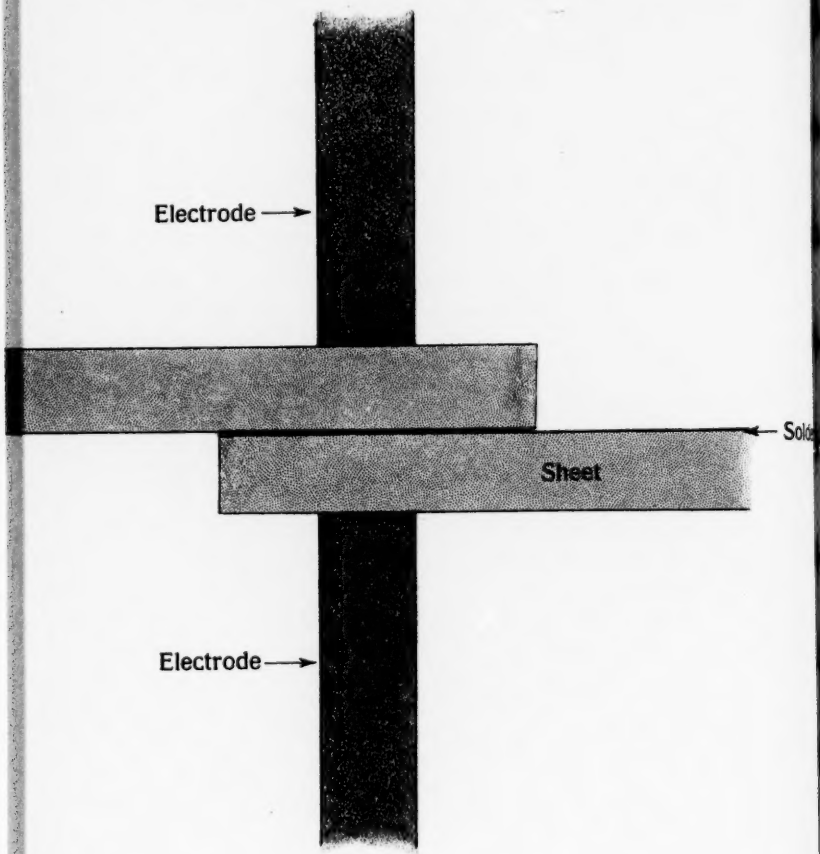
In the accompanying drawing we have illustrated this heating process of the Benardos German patent. The current is conducted through one piece W^1, through the overlap of the sheets and through the other piece W^1; the supply wires are not shown in the drawing. The heat is created in the resistance pieces W^1 by their resistance to the passage of the electric current and is conducted from these pieces to the work.

The German patent distinguishes the process therein described equally from the electric arc welding process of the United States Benardos patent and from the electric

welding process of Thomson, saying (Vol. I, p. 423, 3d paragraph):—

> "*This process is clearly distinguished, both from the point of view of the inventive idea on which it is based and from that of its mode of operation*, from the prior Benardos process of working metals by the direct employment of the electric arc, as well as *from the electric welding process of Elihu Thomson.*"

The Benardos patents, both United States and German, do not relate to electric welding. They contain no suggestion of the idea of making a weld at a spot between two contacting pieces of metal that can take the place of a rivet. These patents are not pertinent to Harmatta's invention.



COFFIN PATENT No. 437,571, SEPTEMBER 30, 1890 (Vol. II, p. 1045).

This patent does not describe a method of electric welding (Gravell, Vol. I, p. 154). It describes a method of heating the ends of two abutting rods held between two anvil blocks of carbon D, D^1 by passing currents of electricity through the rods and through one of the carbon blocks. The idea is to heat the ends of the rods without passing the current directly from one rod to the other. Coffin's object was apparently to avoid the butt-welding process of Thomson in which the current is passed directly from one rod to the other.

There is nothing in this Coffin patent that has any significance, even the most remote, to Harmatta's invention of spot welding.

THOMSON No. 496,019.

ELECTRIC SOLDERING. LOW HEAT. MODERATE PRESSURE.

THOMSON SOLDERING PATENT No. 496,019, APRIL 25, 1893
(Vol. II, p. 1053).

This patent is *not for electric welding* but for "Electric Soldering" (Gravell, Vol. I, p. 156). As the patent states (p. 1, lines 16-23):—

> "My invention consists in clamping or pressing the pieces together at the seam or joint, passing an electric current through either or both of the pieces to be joined, and in sufficient volume to *melt the solder* or uniting metal, cutting off the heating electric current, and maintaining the pressure until the joint is sufficiently cool."

The accompanying drawing illustrates this Thomson soldering process. The electric current flowing from one electrode to the other through the sheets heats them to a comparatively low temperature at which the solder (green) between the sheets melts. When the current is turned off the solder solidifies and thereby unites the two sheets. The solder does not form a weld but is simply a cement or metallic glue for sticking the two sheets together. There is no pressure involved, as in welding, but the sheets are simply held in position while the solder cools and solders them together. When the process is applied to tin plates the tin on the surface of the plate may form the solder (p. 1, lines 12-16).

There is no electric welding and no isolated spot weld is formed. There is no suggestion that two sheets of metal can be electrically *welded* together at isolated spots.

As shown in Figs. 1 and 2, the overlapped edges of two sheets to be soldered together are held between the large electrodes C and C^1 and the solder is melted between their entire areas in contact.

Fig. 3 shows a double lap joint, the parts of which are soldered together.

Figs. 4, 5 and 6 show the soldering together of a round plate P "struck up into form" (p. 2, line 30) and a ring piece P^1 with one edge turned in. The pieces are forced together by the blocks C, C^1 "which may be of iron or other metal" (p. 2, line 37), but Thomson prefers to "face them with a facing such as hard carbon" (p. 2, line 41) in order to concentrate the heat. The facing with hard carbon is shown in black in Fig. 7. This is the same idea as in the Benardos German patent already discussed, namely that of heating the sheets from their backs by means of hot resistance pieces.

Thomson developed the idea further, as shown in Figs. 8 to 17, wherein the ends F of the pressure pieces are provided with small projections, the patent stating:—

> "In all these cases the conduction of heat away from the pieces held between the blocks is greatly checked by the form given to the surfaces as described, and the resistance to the passage of current at the work is increased which in itself results in further production of heat at the sheet metal pieces where pressed up together between the conducting blocks C, C^1." (Page 2, lines 76-85.)

Obviously the heat generated by the small projections and conducted to the work is applied to the back of the pieces to be soldered and would pass through the sheets and melt the solder wherever the heat was great enough. There is no idea here of an isolated spot weld or even of an isolated spot of solder.

Fig. 19 of the Thomson patent shows the pieces P, P^1 rolled together between rollers C^2, C^3, the peripheries of which are grooved as shown in Fig. 20.

Figs. 21 and 22 show a gang soldering machine operating

upon many pieces "in a given time" (p. 2, line 118). A cam S on a shaft D forces down a rod C to clamp the pieces P between its lower end and the upper end of a rod C^1. The continued downward movement of the rod C brings the lower end of the lower rod C^1 into contact with a terminal spring *a* which is connected to the conductor K^1 from the source of electric energy. The upper rod C slides against a spring contact piece connected to the conductor K. As the cam S continues its movement the springs on the rods lift the rods and break the contact between the lower rod and the spring terminal *a* thereby cutting off the current. The continued upward movement of the upper rod C, which is permitted by the cam S, lifts that rod from the soldered pieces P.

There is nothing in this mechanism or mode of operation in the least degree suggestive of spot welding. The solder between the pieces is undoubtedly spread over the entire area of contact of the pieces and would not even form a spot of solder. The electric conductors or electrodes C, C^1 are straight sided rods which would serve neither to carry a current large enough for welding nor to concentrate it at the ends of the rods to a path between those ends only, as are the functions of the taper ended electrodes of Harmatta's invention. Such straight sided electrodes as are shown in this Thomson patent might be suitable for electric soldering but they would be utterly useless for electric welding.

Furthermore the electric contacts for closing the circuit would be unable to carry the heavy current necessary for electric welding.

This Thomson patent does not even teach the art how to make a soldered joint except throughout the area of contact of the pieces to be soldered. Even therefore if the arts of soldering and welding were in the least analogous, which they are not, this Thomson patent would be in no

way suggestive of Harmatta's idea of making a spot weld between the contacting surfaces of two plane sheets in extended indiscriminate facial contact.

This Thomson patent discloses only soldering operations. It contains no thought or suggestion that such a weld might be made at any place between two such plane sheets.

It offers no solution of the problem of how to concentrate a welding current at a spot in the meeting surfaces of two plane sheets in extended facial contact.

It offers no solution of the problem of how to apply pressure as is necessary in welding to complete the weld between two such sheets.

While soldering and welding both require the application of heat to the metals being treated they are in other respects in no way alike. Welding results in an autogenous union of the two metal sheets. Soldering results in the mere metallic gluing together of the pieces.

Welding requires a current sufficient to raise the parts to be welded to a temperature of 2400° F. Soldering requires a current sufficient to raise such parts only to a temperature of 400° F (Dyer, Vol. I, p. 599). The manipulation of a welding current for spot welding presents a very different problem from the manipulation of a soldering current. The former requires increased resistance at the welding point, provided by a marked reduction of the cross-sectional area of the work at that point as in the art prior to Harmatta, or provided by tapered electrodes as in the Harmatta process.

The soldering current requires no such concentration of resistance or concentration of current.

In the Harmatta process the ends of the electrodes, although small in area, are not the source (except as carriers of the welding current) of the welding heat which is generated at the joint between the work. In the Thomson soldering process in most of the figures of the

patent illustrating that process the ends of the electrodes are faced with carbon or are grooved or corrugated so that those ends shall offer material resistance to the current and become heated and thereby heat the work. This is the antithesis of Harmatta's idea of creating a welding heat solely at the joint between the two pieces to be welded.

In the electric soldering of the Thomson patent there is nothing in any way resembling Harmatta's method of applying pressure solely to the opposite sides of the spot to be welded. In Thomson the sheets or plates are not heated highly enough to make them soft and therefore the application of such pressure as is needed for soldering at most merely pushes those sheets bodily towards one another, if that can be done, by squeezing out some of the solder between the sheets.

The Thomson patent does not involve or suggest Harmatta's idea of completing a spot weld by pressing firmly but slightly on the softened metal on each side of the spot to be welded without the bodily movement of the sheets themselves.

This Thomson soldering patent No. 496,019 contains no suggestion of the electrode spot welding process of the Harmatta patent. Ten years elapsed from its date of issue in 1893 before Harmatta, who was the first to do so, thought of the electrode spot welding process.

BLANCHARD PATENT No. 466,266, DECEMBER 29, 1891 (Vol. II, p. 1051).

This patent does not describe a process of electric welding or even of uniting two pieces of metal. It is for an "electric heating tool" consisting of a pair of pincers, the ends of which are provided with electrodes *b*, *b*, between which the article to be heated, such as a rivet, is grasped. An electric current is then passed from one electrode to

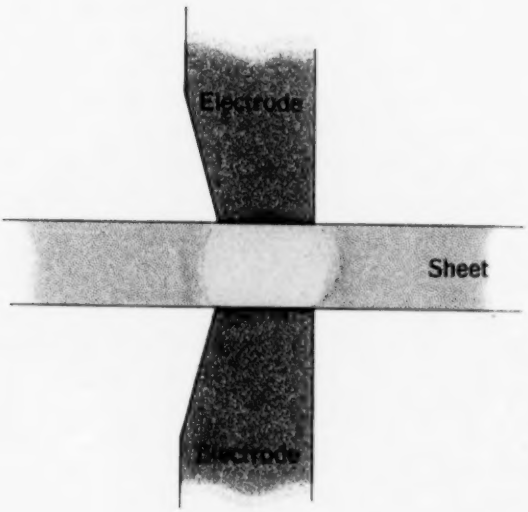
the other through the article and thereby the article is heated.

This patent has no conceivable relevancy to the Harmatta patent in suit (Gravell, Vol. I, p. 158).

LEMP PATENT No. 531,197, DECEMBER 18, 1894
(Vol. II, p. 1058).

This patent is not for electric welding (Gravell, Vol. I, p. 159), or even for uniting two pieces of metal. It is for a "method of producing locally annealed steel plates" and shows a process of passing an electric current through a single steel plate at a place which it is desired to soften or anneal in the hardened plate. The current does not cross a joint between two plates or sheets.

The process has nothing whatever to do with electric welding, as no weld is attempted to be made, and is merely a specific example of the old process of heating an article by passing a current of electricity through it. It is entirely immaterial that in some cases the electrodes employed by Lemp are pointed, as for example in Fig. 4, because there is no suggestion or hint by Lemp that by such means an electric weld could be made between two thin sheets of metal in contact with one another. There is no hint of Harmatta's idea in this Lemp process.



The process is illustrated in the accompanying drawing. The part colored red is that heated and softened.

BURTON PATENT No. 647,694, APRIL 17, 1900
(Vol. II, p. 1079).

This patent (Gravell, Vol. I, p. 161) is not for electric welding but for an "Electric Metal Working Apparatus" and shows means for electrically *heating* the ends of rods and other articles by means of passing electric current therethrough *so that they can be afterwards hammered together on a blacksmith's anvil*, which is illustrated at 110 in Fig. 1 of the Burton patent. As the patent states:

LEMP No. 531,197.

LOCAL ANNEALING.

No Welding.

No Pressure.

"The object of the invention is to provide a simple, convenient and compact apparatus for the use of a blacksmith or other metal-worker." (Page 1, lines 22-25.)

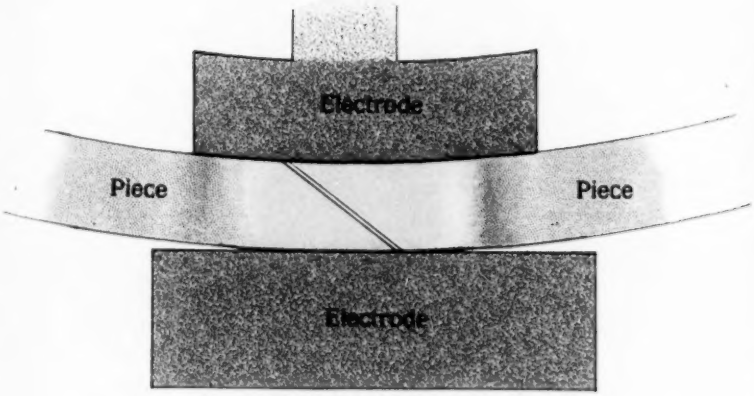
According to the described process, electrodes of various shapes are pressed against opposite sides of the work and a current is passed from one electrode to the other through the work, thereby heating it to welding temperature. In all cases where there are two pieces of metal or two ends of a ring or other kinds of pieces to be welded together, *the pieces of metal or the ends of the work are shown separated from one another and not as being pressed together by the electrodes.* The current does not cross the joint between the two pieces but divides and passes through the end of each piece separately. It merely heats the ends of the pieces, and there is no suggestion of forming a weld by pressing the work together by means of the electrodes. On the contrary, the patent states:—

"*As soon as the piece is heated to the proper temperature,* which may be ascertained by inspection thereof, *the operator releases the foot-lever* and the spring 170 lifts the hinged lever 150 and takes the upper electrode out of contact with the work, whereby the circuit is broken. *Then the operator may shove the work forward on the anvil and hammer the joint or otherwise finish it, as desired.*" (Burton patent, p. 2, lines 78-87.)

The release of the pressure when the work gets hot is the antithesis of the Harmatta process in which pressure is applied at that moment to make the weld.

The Burton process of heating is illustrated in the accompanying drawing. The ends of the work, which are slightly separated from one another, both rest upon the lower or bed electrode and are clamped thereto by the

upper electrode, which also is in contact with both ends. The current flows from one electrode to the other in two paths, one in each end of the work, and heats those ends to a welding temperature as shown in yellow. The patent describes no means for welding the two ends thus heated, but it suggests, as above quoted, that they may be removed to an ordinary anvil and hammered together. The Burton patent does not describe electric welding.



It is entirely immaterial that among the tools shown on the electrode head 200, there is illustrated a tool with spherical end 240 and a tool with a pointed end 250. There is no description whatsoever in the patent as to how these tools are to be used and no suggestion whatever that they could be used for making a spot weld or a weld of any kind. Figs. 3 and 4 show the use of the pointed tool entering a hole in a single sheet as if to spread and taper its mouth. Undoubtedly the spherical tool was intended for use for a similar purpose, which is not welding at all. In fact, as we have already pointed out, Burton's idea was merely to heat articles some of which were afterwards to be welded by the blacksmith on his anvil.

If either the pointed electrode or the spherical electrode were used in connection with the overlapped ends of the work they would not produce a weld even if the ends of the work, contrary to Burton's showing and expressed purpose, were in contact. The reason is that the end of the pointed or spherical electrode could contact with one end only of the work and as that end is also in contact with the bed electrode 100, the current, which follows the shortest and easiest path, would pass through that end only and would not cross the joint between the ends of the work and would not heat the other end. Therefore no weld could possibly result.

Even if the point of the pointed electrode or of the spherical electrode were placed precisely on the crack of

BURTON No. 647,694.

HEATING.

Ends of pieces are separated, i. e., not in contact.

Current traverses end of each piece separately; it does not cross the joint.

Pieces heated are removed to an anvil, and there welded by hand.

the joint between the ends of the work (which Burton does not describe or suggest), no weld would result because the current would split and pass in two branches, one through each end of the work to the bed electrode 100 on which both ends lie in contact as in the cases of the use of the large electrodes shown by Burton.

Moreover, the Burton patent does not describe or even suggest the application of pressure by the apparatus for the purpose of welding.

There is in the patent no disclosure or suggestion of spot welding. This patent was set up in the answer in the Barney & Berry case in the First Circuit, but was not thought of sufficient consequence to be discussed by the defendant's experts in that case. It has remained for the ingenuity of Mr. Dyer, defendant's expert in this case, to suggest reading into the Burton patent a description or suggestion of spot welding. No one, not even Burton himself, had thought of this before. There is no foundation for Mr. Dyer's suggestion.

THOMSON RIVETING PATENT No. 396,015, JANUARY 8, 1889 (Vol. II. p. 1037).

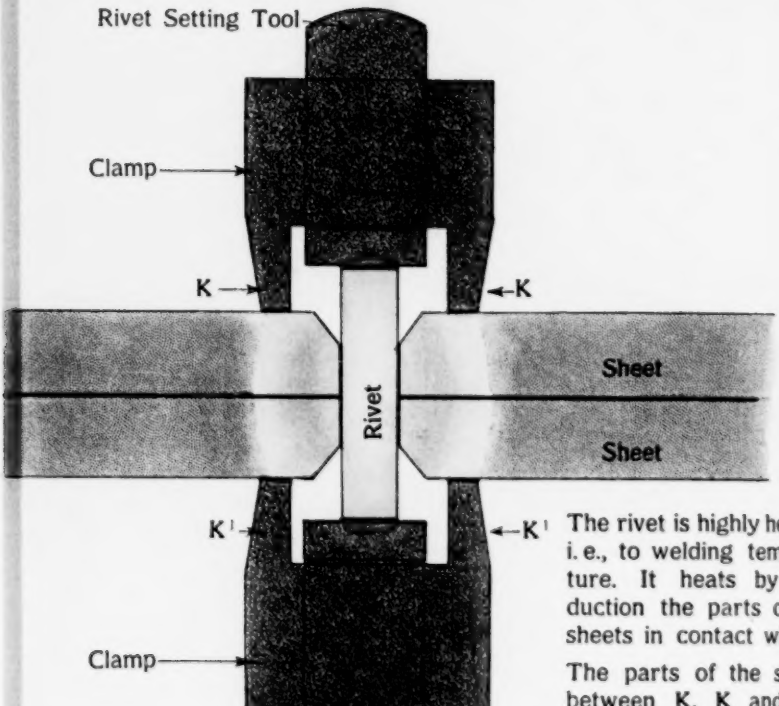
The patent (Gravell, Vol. I, p. 165) is not for electric welding but for a method of "electric riveting". It describes *the heating of a rivet* by passing an electric current therethrough between the anvil E^1 and the plunger G, which are in contact with the ends of the rivet and are the rivet setting tools. The rivet is headed by squeezing the rivet between the anvil and the plunger.

Another idea developed in this Thomson patent is that of partially welding the rivet to the sides of the hole. To accomplish this Thomson maintains the electric current through the rivet long enough to heat it highly so that enough heat is *conducted* from the rivet to the sides of the

rivet hole to raise the contacting metal to welding temperature. Then when the rivet is compressed and headed it is partially welded to the metal at the sides of the hole.

Concerning this operation the patent states:—

> "A valuable effect, (illustrated in Fig. 6) not possible in other processes, may be obtained in my method of riveting by continuing the heating on the rivet-blank placed in the hole for some moments longer than is necessary to raise it to a softening temperature. *By conduction* the heat is carried to the portions of the plate surrounding the rivet, raising such portions to a welding temperature, and when the rivet is pushed firmly into the hole *a partial welding of the rivet to the sides of the hole is effected*, thus forming practically solid metal for a portion of the distance from d to d^1." (Page 2, lines 28-41.)



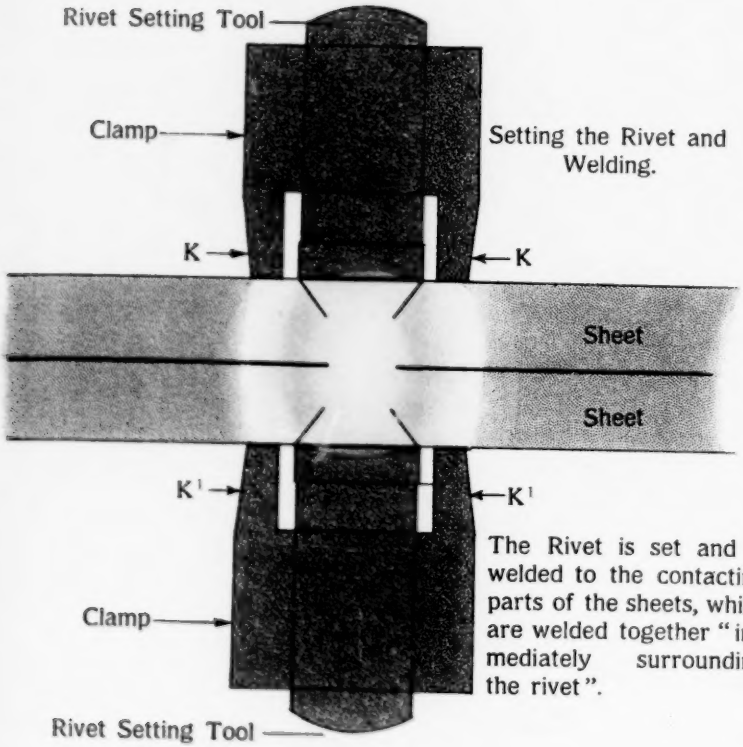
Thomson recognized that the squashing of the rivet between the anvil and the plunger would tend to separate the plates, and therefore provided clamps K, K^1 for holding the plates together, as shown in Fig. 9. The body of the clamp K is screw-threaded in the support B^1 so that the clamp may be screwed down onto the plates. Thomson provides mica pieces m, m^1 between the ends of the clamps and the plates in order to insulate the clamps from the plates. He, however, states that these mica pieces may be dispensed with and that part of the current of electricity may flow through the plates from one clamp to the other. The purpose of this is merely to assist the heating of the rivet and the parts of the plates in contact with it. Of this the patent states:—

> "By the use of this form of apparatus a heating electric current might be passed through the metal plates themselves at parts around the rivet by means of the pressure pieces or clamps K, K^1. Such current

THOMSON No. 396,015.

ELECTRIC RIVETING.

HEATING.



The rivet is highly heated i. e., to welding temperature. It heats by conduction the parts of the sheets in contact with it.

The parts of the sheets between K, K and K, K¹ are heated by the current, to assist the heating of the parts in contact with the rivet to welding temperature.

THOMSON No. 396,015.

ELECTRIC RIVETING.

PRESSING.

The Rivet is set and is welded to the contacting parts of the sheets, which are welded together "immediately surrounding the rivet".

No welding pressure is applied to the clamps.

would assist in raising the portion of the plates *immediately surrounding the rivet* to the welding temperature; but the prime object is that through the application of the pressure the plates themselves may be held together during the riveting. The blocks K^1, K may therefore be faced with mica or other insulator, m, m^1." (Page 2, lines 68-80.)

We have illustrated in the accompanying drawings the operation of welding the rivet to the metal at the sides of the hole while the plates are held firmly against one another by means of the clamps, in which operation part of the current flows from one clamp to the other.

The first drawing shows the heating effect by which the current passing through the rivet and overcoming the resistance thereof raises the rivet to a high temperature, as shown in yellow. The heat of the rivet is conducted to the metal at the sides of the hole, also shown in yellow. The current flowing between the clamps heats the metal at a short distance from the rivet, as shown in red, and this heat acts to assist the heating of the rivet and of the sides of the rivet hole, as Thomson points out.

Our second drawing shows the heading of the rivet. In this case the heads of the rivet are set into the countersunk holes in the plates and the body of the rivet, which tends to squash out sidewise under the riveting pressure, is welded to the metal at the sides of the hole.

Professor Thomson in his affidavit filed in connection with the Rietzel application accurately states of this process (Vol. III, p. 1786):—

"My prior patent No. 396,015 discloses the use of rivets and makes mention of welding but the only possible welding that could be produced by that process would be possibly some sticking of the edge of the perforation in the metal sheet to the side of the

rivet which is a mere incident of the invention and there is no welding of the superposed plane surfaces or opposed faces of the plates to one another by welds disposed over such plane faces."

Mr. Dyer, defendant's expert, seems to think that this Thomson patent in some way foreshadows Harmatta's invention. Inasmuch as *Thomson's idea was to insert a rivet* to unite two sheets of metal and *Harmatta's idea was to avoid the use of a rivet* and to unite such two sheets by means of a spot weld between the two sheets of metal, it is difficult to imagine two processes which could be more fundamentally antithetical to one another. Thomson had no idea whatever of any process in which a rivet could be dispensed with. *To dispense with a rivet was the fundamental thought of Harmatta.*

The defendant's suggestion, that by some totally unauthorized manipulations of the apparatus shown in the Thomson patent a spot weld might be made, are entirely irrelevant. This suggestion is based upon the supposed effect of the clamping devices K and K^1 of Fig. 9 if arranged and operated in a manner for which there is no warrant in the Thomson patent. Defendant's idea is that if these clamps were placed directly against the plates, after removing the insulation pieces m, m^1, and *if* their respective clamping points came opposite to one another, and *if* the right current of electricity were passed from one set of clamping points K through the work to the other set of clamping points K^1, there would be spot welds between the plates in their meeting surfaces at the spots in line with the opposed clamping points.

There is no hint of any arrangement or operation of this sort in the patent. Electrically the proposition is entirely unsound. When the pieces of mica m, m are removed it would be necessary to set up the screw clamp

S' to clamp the work between the arms K, K'. This turning of the screw would throw the clamping arms out of alignment and hence would prohibit the making of spot welds as suggested by Mr. Dyer. There is, moreover, no suggestion whatever in the Thomson patent that during the process the clamping arms are moved towards one another, hence *the pressure necessary for making a weld in line with the clamping arms (even if they were in line) would be lacking.* The only parts that are moved in the process of this Thomson patent are the electrode riveting tools G, G' which abut against the ends of the rivet. They are moved by the screws X, X' to set the rivet. The patent does not suggest that welds between and in line with the clamps might be made and none in fact could be made.

The uniting of the sheets and the rivet together by this Thomson process is not electric welding in any sense, because the heating of the plates is accomplished entirely by conduction of the heat from the heated rivet and not by the passage of current through the sheets as in electric welding.

The process further differs from that of the Harmatta patent in suit in the employment of a rivet as an essential instrumentality in the process which it was the object of Harmatta to dispense with, substituting therefor a spot weld. This Thomson process does not result in a spot weld and is not in any sense the process of the Harmatta patent in suit.

No one of the foregoing prior patents is for an electric welding process.

We now come to the patents on electric welding processes. No one of them even approaches the problem, solved by Harmatta, of welding together two thin sheets of metal *at any spot* in their meeting faces. That was a new idea first introduced into the art of welding by Harmatta.

THOMSON PATENTS Nos. 347,140 AND 347,141 of 1886 (Vol. II, pp. 1021, 1026).

These Thomson patents show and describe for the first time the process of electric welding, but they disclose only how it may be applied to joining together the *butt ends* of two metallic rods by passing an electric current of low voltage and high amperage from one rod to the other and pressing the two rods together. This specific process was of great value and went into commercial use, where the process became known as "Butt Welding".

We have fully discussed these patents *supra*, pp. 6–8.

THOMSON ROLLER LAP WELDING PATENT No. 444,928, JANUARY 20, 1891 (Vol. II, p. 1047).

Of the many patents in the prior art to which defendant has called attention this Thomson patent for roller lap welding is the one which has been especially emphasized.

In the suit of *Thomson Electric Welding Company* v. *Barney & Berry*, brought on the Harmatta patent in the United States District Court for the District of Massachusetts, particular reliance was placed on this Thomson roller patent by Judge Dodge in the District Court who found the Harmatta patent invalid for lack of patentable quality. The opinion of Judge Dodge is reported in 227 Fed. 428-433, see especially page 431.

The Court of Appeals for the First Circuit in finding the Harmatta patent valid and reversing the decree of the District Court also carefully considered this Thomson roller patent, saying 227 Fed. 435:

> "Returning to the defenses based on the roller electrode process, or other processes devised with reference to overlapping sheets, it is all too plain that neither in its practical operation nor in its result was there any resemblance to the spot welding such as to require discussion."

The majority opinion of the Circuit Court of Appeals for the Sixth Circuit in the case at bar lays particular stress on this Thomson roller welding patent as part of the prior art which the court regarded as negativing patentable invention by Harmatta. (Vol. III, pp. 2099, 2100).

The reason why this Thomson lap welding roller patent has attracted more attention than any other item of the prior art is clear. It alone of the disclosures of the prior art relates at all to the welding of plane flat sheets of metal and it is with the welding of plane flat sheets of metal that the Harmatta patent deals. But the resemblance between the two inventions begins and ends with this single and immaterial circumstance. The Thomson roller patent No. 444,928 is an application of the fundamental Thomson invention of electric welding to the *continuous welding of lap welded plates at their edges*, which had been done before by other methods of welding. The Harmatta invention relates to the application of the same fundamental principle of electric welding *to the isolated union of two plane sheets in spots* wherever there may be occasion to unite them which had never been done before by any method of welding. It substitutes electrically welded spots for the rivets that had been invariably used for such a union. The Harmatta principle and method of operation and its result were in all respects novel and not in the slightest degree foreshadowed in the disclosures of the Thomson lap welding roller patent.

Thomson's roller process was designed and adapted only for welding the lapped edges of sheets. This had previously been done, as in lap-welded pipe for instance, by ordinary blacksmith methods in which the edges of the sheets could readily be heated at a forge or by a plumber's torch or otherwise, then overlapped and hammered or rolled together into an integral weld. There was no difficulty in doing this.

But this did not instruct any one how to make an isolated weld anywhere in the meeting faces of two sheets. The only method that we can think of for heating the parts of such sheets to be welded would be to apply a plumber's torch to the spot in each sheet separately. The heat could not be applied to the sheets when placed one on top of the other, because there would be no way of applying the heat to the meeting faces of the sheets. Heating them from the backs would be inadequate and would result in merely melting holes in the backs of the sheets as we have explained as to the United States and German Benardos patents (*supra*, pp. 23–24).

Then having thus heated by a plumber's torch the spots in the sheets to be welded, it would be necessary to place those sheets face to face in the exact position so that the heated spots would come against one another. While the sheets were being so placed the heat from the spots would be dissipated. So that if an attempt were then made to place the sheets on an anvil and hammer the spot, it would be suprising if the metal remained at welding temperature long enough for this hammering to be carried out. Moreover, the backs of the sheets being of relatively cold metal might not yield sufficiently to the blows of the hammer to force the heated spots together into a real weld.

The welding of overlapped edges of sheets whether by blacksmith methods or by electrical methods therefore taught no one how to make a weld at any point, however remote from their edges, in the meeting faces of two sheets in undetermined extended facial contact.

This Thomson lap welding roller patent (Gravell, Vol. I, p. 175) describes a proposed process of lap joint welding between two wide roller electrodes. As above stated, the contentions based upon it, adverse to Harmatta, have been considered in every proceeding in which the Harmatta patent has been involved.

The patent was cited against Harmatta's application and was fully considered by the Patent Office (Vol. II, p. 1380, etc.).

In fact the process of this Thomson patent is referred to in the Harmatta patent itself (Vol. I, p. 388) as follows:—

> "It has also been proposed to make a lap joint between the ends of two strips of metal by electrically uniting them together over substantially the whole area of the lapping surfaces.
>
> "A weld formed according to my invention is distinguished however from such prior welds, among other things, by the fact that the opposed surfaces available for uniting the pieces together and in which it might be possible to form a weld are welded in a small spot or spots only, the spot or spots being surrounded by comparatively large areas of opposed surfaces in which no weld is made." (Page 1, lines 42-56.)

The Thomson roller patent states:—

> "My invention relates to a process of electric welding in which *the surfaces to be welded* are pressed together to form a union, and the heating of the surfaces to the desired plasticity is effected by means of an electric current passed across the joint or line of proposed union." (Page 1, lines 8-14.)

The process so far stated is merely the butt welding process of Thomson's basic patents in which *the surfaces to be welded* are heated and pressed together.

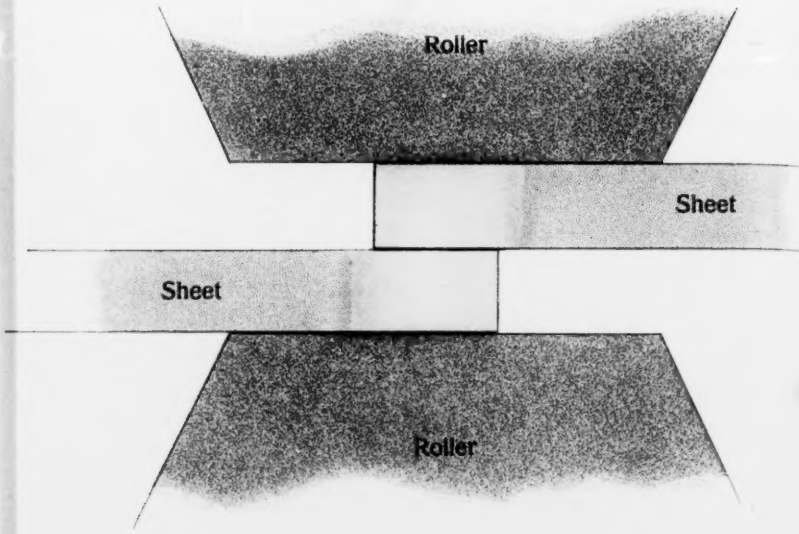
The Thomson roller patent continues:—

> "My present invention relates more particularly to the process of joining or welding together strips, sheets, plates, or bars of metal where it is desirable to form a joint of considerable length, and is especially applicable to the welding of plates together at their edges, instead of riveting, to the welding of ribs or

> strips of metals to plates for the purpose of strengthening the same, to the formation of pipes by welding a longitudinal joint, to the welding of half-round or other shaped strips on one or both sides of a plate or strip of metal, and to other similar classes of work, as will be obvious." (Page 1, lines 15-28.)

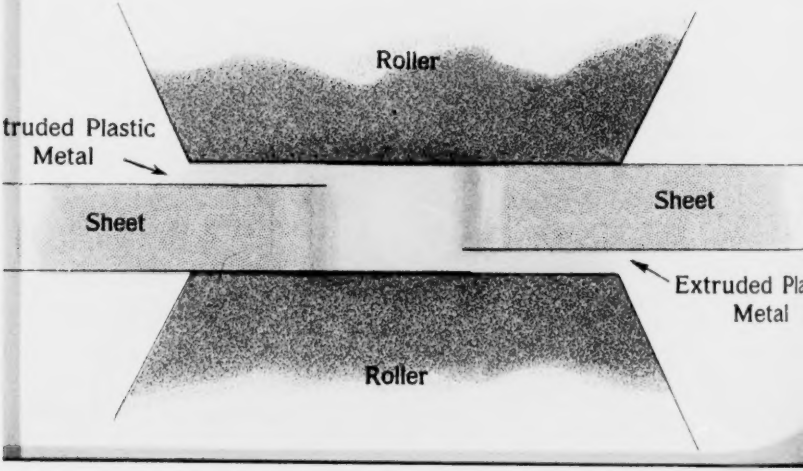
All these suggested applications are of the same class and the same character. They involve the same idea, of which the specific example, relied on as suggestive of the Harmatta invention is "the welding of plates together at their edges, instead of riveting". Thomson is merely seeking to substitute a long continuous weld between the overlapped edges of plates for a series of rivets. This is not at all Harmatta's idea of forming a single weld, which would take the place of a single rivet, *made anywhere* between the meeting faces of two sheets or plates in extended contact. Thomson welded only at the overlap of the edges of the two plates. He could not weld at any other point.

The Thomson patent further states:—



> "My present invention consists, essentially, of forming *an elongated joint* by the electric welding process by feeding the work in the longitudinal direction of the joint through suitable pressure devices, *the work being properly arranged*, so that the pressure devices will press the surfaces to be welded together and simultaneously passing an electric current through the work at the point of pressure." (Page 1, lines 29-38.)

As shown in the drawings of the patent the work is "*properly arranged*" by overlapping the edges of the two sheets or plates, as in cross-section in Fig. 1. The work so arranged is placed between two rollers R and R^1, the latter being forced towards the roller R by the screw S, the patent stating:



THOMSON No. 444,928.

ROLLER LAP-JOINT WELDING.

HEATING.

PRESSING.

> "The edges of the two plates are slightly overlapped, as shown, and the plates, being in position between the rolls, may be squeezed together by means of the screw S, thus forming an electric contact between them." (Page 1, lines 85-88.)

The essence of this arrangement of the plates and the electrode rollers is that the heavy welding current passing through the heavy conducting cables C, C^1, through the frames F, F^1 and through the rolls R, R^1 has traversed a path of low resistance but when it reaches the work it is forced through the comparatively narrow path formed by the overlap of the work itself and because this overlap is narrow, being much less than the width of the rollers, the resistance of this path is high. Hence the heavy current meeting this high resistance *in the narrow overlap* of the plates heats the metal of that overlap to welding temperature. This condition is illustrated in the figure marked "Heating" in the accompanying drawing.

The Thomson patent states:—

> "The electric current being now turned on as it passes from one roller to the other and across the point of pressure will heat the work to the welding temperature and soften the same slightly, after which the screw may be given a few more turns to effect a solid union." (Page 1, lines 88 to 95.)

The effect is illustrated in the figure marked "Pressing" in the accompanying drawing.

This is the same mode of operation which Thomson describes in his earlier basic patents, namely the contacting parts of the pieces to be welded (the overlap of the sheets or the ends of rods) are pressed together by large heavy electrodes. The current is forced across the narrow path provided by those contacting parts and there meets high resistance due to the limited cross section of those parts so that it heats those parts to welding temperature. Then

the pressure applied forces the pieces bodily together "to effect a solid union". All this was nothing but the method of the early Thomson patents applied to the welding of overlapped edges of sheets instead of to welding the butt ends of two rods. *In both cases the high resistance of the small cross-sectional path of the contacting parts of the pieces to be welded is what causes the current to create the heat necessary for welding.*

The Thomson roller patent then continues and describes the new feature of the roller process:—

> "The work, having been thus started, may now be moved along through or between the rollers, so as to bring successive parts of the joint into position to be pressed and heated at the same time. By this operation the metal will become thoroughly united as it passes through and out from between the rolls." (Page 1, line 94, to p. 2, line 7.)

That is, the rollers, having been brought closer together than the combined thickness of the two sheets, perform a sort of drawing operation on the edges of the sheets by pressing them bodily together as the sheets are forced between the rollers.

In this way Thomson proposed to weld together the previously arranged overlapping edges of two metal sheets.

In the Thomson process, it is absolutely necessary to maintain the extent of the overlap exactly right all the time. If the overlap is too great, its resistance will be too small and the current will not heat the overlapped edges sufficiently and no weld will be made. If the overlap is too small, the resistance will be too great and the current will overheat the overlapped edges, perhaps melting or burning them. To keep the overlap uniform is "almost impossible in commercial work" (Gravell, Vol. I, p. 176).

It may be noted that the welded seam back of the rollers is very hot and hence is of high resistance and thereby any tendency of the current to flow from one sheet to the other through the parts already welded is resisted. Also, as shown in Figs. 2 and 3 of this Thomson patent, which figures illustrate the process as it is being carried out, the sheets to be welded are shown as divergent as they are being fed to the rollers, so that in advance of the rollers there is no metal through which the current may flow. Hence the current is confined lengthwise of the seam to the parts being welded between the rollers by the high resistance of the hot metal back of the rollers and by lack of contact of the sheets ahead of the rollers.

It is confined crosswise of the seam by the limited extent of the overlap of the sheets.

Hence in the Thomson roller process the current is confined to the parts being welded by the arrangement of the work on three of the four sides, namely in both directions crosswise and in the direction ahead of the rollers. In the direction back of the rollers, it is confined by the high resistance of the adjacent highly heated metal.

THOMSON'S LAP WELDING ROLLER PROCESS A BUTT WELDING PROCESS.

As shown by our earlier discussion of the basic electric welding Thomson patents Nos. 347,140 and 347,141 (*supra*, p. 6), the butt welding process consisted of placing in contact *only those parts of the pieces* which were to be welded, thereby providing a path of limited cross-section and consequent high resistance for the passage of the current; then passing a heavy electric current through the restricted path provided by the parts in contact thereby heating those parts adjacent the joint to welding temperature; and then pressing or bodily forcing the two parts towards one another so as to complete the weld.

These steps, which are characteristic of butt welding, are carried out in the Thomson roller lap-welding process. *First*, the two plates are arranged in proper relation, namely with their edges slightly overlapped, thus providing a comparatively narrow and limited path of high resistance for the passage of the current; *second*, the current is passed from one sheet to another through that path, the current being confined thereto *by the arrangement of the sheets themselves*, and *third*, the two plates are forced bodily together by the rollers to complete the weld. The Thomson roller process is therefore a butt welding process.

The Thomson roller process was deemed patentable and the patent issued therefor because Thomson there dealt not with the butt ends of two metal rods, as in his earlier patents of 1886, *supra*, but with the overlapped edges of two metal sheets and because he employed rollers to make a continuous lap weld instead of merely forcing the ends of two rods together, as in those earlier patents.

But where in this Thomson patent is Harmatta's idea of making a single small weld, or a series of such welds, at any place in the meeting surfaces of two plane sheets of metal indiscriminately superimposed upon one another without regard to the extent of the area of contact?

There is no such idea in this Thomson roller patent and nothing that suggests that idea. Thomson's roller patent therefore did not disclose or suggest to anyone Harmatta's result, namely a spot weld perfectly answering the purpose of a rivet placed at any desired point.

The Thomson roller patent therefore is absolutely devoid of any trace of the first and most important element of Harmatta's invention, namely *the idea* of a spot weld between two plane sheets at any place in their meeting surfaces. It therefore can not in any sense be taken as suggestive of Harmatta's invention.

This should be sufficient to dispose of this Thomson

roller patent as an alleged disclosure or suggestion of the Harmatta invention regardless of any other considerations.

But suppose that Thomson or someone else had had the thought suggested to him that it would be a useful and desirable thing to make a weld at any place in the meeting surfaces of two plane sheets of metal, how would the disclosure of the Thomson patent aid him in accomplishing that result?

Thomson describes overlapping slightly two sheets at their marginal edges only and thereby confining the current to the overlap where the sheets are welded. This would not suggest to anyone the placing of two plane sheets, one on top of the other, in unlimited and unpredetermined facial contact without any regard whatsoever to the points at which they were to be welded together. Thomson therefore did not teach the manipulation or the possibility of the manipulation of plane sheets with which Harmatta was dealing and which is a characteristic of his invention.

Electric welding is based upon the idea of providing a high resistance to a heavy current at the place of welding. When the pieces to be welded are in contact over a relatively small cross-sectional area as in the Thomson roller patent, that arrangement by the very restriction of the path offered to the current provides the necessary high resistance. But if there are two sheets indiscriminately superimposed upon one another with an unlimited extended area of contact, as in the Harmatta process, a path of relatively great cross-sectional area is provided at the place of welding, *i. e.* between the sheets, for the passage of the current. That path of great cross-sectional area would therefore provide relatively small resistance. As high resistance is needed in electric welding, how is it to be obtained when the conditions seem to prohibit it? That was one of the problems solved by Harmatta, who solved it by a new functional use of pointed electrodes.

Did Thomson in his roller lap welding patent disclose or suggest the solution of this problem? Certainly he did not. He was not even dealing with that problem. He was adhering to the old idea of providing high resistance at the place of welding by limiting the cross-sectional area of the parts in contact. He had no notion whatever of how to provide the necessary resistance without such a restriction of contact of the work itself. Harmatta's problem of providing the necessary high resistance between sheets in unlimited unpredetermined facial contact was not approached, much less solved by Thomson. Without a disclosure of the way to solve that problem the Thomson patent is in no sense suggestive of the Harmatta process.

The Thomson patent describes the use of *roller* electrodes to make a continuous electric lap weld. This idea is not only lacking in suggestion of, but is positively antithetical to Harmatta's idea of a single weld made at any point between the meeting faces of two plane sheets of metal.

The Thomson patent describes *wide rollers* as his electrodes, rollers much wider than the overlap of the sheets to be welded. How are these rollers to be used to make a small round weld at any place between two sheets in extended facial contact? How could they make a weld away from the edges of the sheets? It would be impossible. No one has ever so made such a weld so far as this record shows.

Harmatta devised an absolutely new form of electrodes, namely, pointed electrodes to get his result of a spot weld by concentrating the current solely by the electrodes. Thomson's rollers could not do that.

The Thomson roller patent describes the completion of the weld by the bodily movement of the two sheets towards one another, with an incidental squeezing out of the metal, a characteristic of all welding known before Harmatta's invention. In the Harmatta process there is no squeez-

ing out of the metal. When two superimposed plane sheets are in extended facial contact, as Harmatta arranges them, they can not be moved bodily together. The Thomson roller patent sheds no gleam of light on the solution of this problem of applying the welding pressure without bodily moving the parts. Neither Thomson nor any one else in the art prior to Harmatta had even realized or attacked this problem, much less solved it.

To sum this matter up:—

1. The Thomson roller patent does not suggest Harmatta's radically new idea of a spot weld uniting two plane metal sheets in unlimited extended facial contact at any desired point in their meeting surfaces. Without this idea Harmatta's invention is non-existing.

2. The Thomson patent does not suggest the manipulation of the two sheets so that they be in extended facial contact which is a characteristic of Harmatta's invention, which no one before Harmatta ever suggested and which was a condition under which no one before Harmatta had ever thought that a weld was possible.

3. The Thomson roller patent does not suggest how to solve the problem of welding two indiscriminately superimposed plane sheets in extended facial contact at any point in their meeting surfaces. Thomson disclosed nothing more than the old butt welding idea of providing the necessary high resistance to the passage of the current by restricting the cross-sectional area of the parts in contact. He makes no suggestion of how to concentrate the current to a small spot in sheets in extended facial contact so as to heat only that spot to welding temperature. Neither Thomson, nor anyone else before Harmatta, had any conception of any way of providing that resistance or of preventing the current from spreading out all over two sheets in extended facial contact and passing between those sheets throughout the area of contact, whereby the

resistance to the passage of the current would be so low that no welding heat could be obtained.

4. The Thomson roller patent does not suggest the pointed electrodes, which are a new and essential means in the Harmatta process. Thomson's rollers could not be used, and never have been used to make a spot weld.

5. The Thomson roller patent offered no suggestion of a solution of the problem of how the welding pressure was to be given the parts to be welded without bodily moving the sheets together, which is impossible with two sheets in extended facial contact as in the Harmatta process. Harmatta solved that problem by the invention of a new technique performed by his pointed electrodes (*supra*, p. 15).

The Thomson roller patent therefore suggests neither the idea of making a Harmatta spot weld nor any ideas that would be useful in solving the problem of how to make such a weld.

Now that Harmatta has disclosed not only the brilliant and original conception of a radically new result, namely a spot weld between two plane metal sheets, but also the way to solve the technical problems involved in making that spot weld, the whole thing may seem simple. But it is no more simple than the idea of putting the eye in the point of the sewing-machine needle or the idea of the constant contact of the electrodes in a microphone, but it took the genius of an inventor to think of these revolutionary ideas and in Harmatta's case also patentable discovery and invention of high order.

The Court will look at Harmatta's invention from the point of view of the knowledge of the art as it existed before December 3, 1903, the date of Harmatta's application for the patent in suit. It will find nothing in that art descriptive or even suggestive of Harmatta's invention. It will find nothing of the kind in the Thomson roller

patent above discussed, which is that item of the prior art which has been regarded as more suggestive of Harmatta's invention than any other, only because it dealt with two sheets in lapped contact (but only at their edges) where the weld was to be made and therefore had a misleading superficial resemblance to Harmatta's sheets which were also overlapped or placed one on top of the other but were not to be welded for the whole overlap but only at selected spots. But the distinction that Thomson's overlap was limited in extent and position as a necessary feature of his process, while Harmatta's overlap is unlimited and its extent or position is utterly immaterial to the welding process, is of the utmost significance.

LEMP PATENT No. 553,923, FEBRUARY 4, 1896
(Vol. II, p. 1065).

This patent (Gravell, Vol. I. p. 178) illustrates and describes a scheme using rollers, as in the Thomson patent No. 444,928, for—

> "Forming of long joints between strips, bars, plates or rods—such as boiler plates or other articles which are at present riveted—by welding, soldering, cementing or similar operation" (page 1, lines 24-28),

and the invention consists—

> "In applying to the metal heating electric currents of different frequency during the manipulation thereof." (Page 1, lines 16-18.)

Lemp's idea was to pre-heat the work, which consisted of two strips diagrammatically illustrated in the drawings, by means of two or more alternating currents of different frequency. He used several transformers, shown for example in Fig. 3, and a number of contacts bearing upon the work and so arranged the polarity of his circuits that through a part of the work the currents flowed lengthwise

of the work and through other parts of the work it flowed crosswise between the electrodes. His entire object was *to pre-heat the work* so as to deliver it in a heated condition suitable for welding between the final pair of roller electrodes.

There was no suggestion in this Lemp patent of Harmatta's invention of welding together two sheets of thin metal at any spot or place in their contacting surfaces by means of pointed electrodes which concentrate the current and pressure at the spot or place to be welded.

There is nothing in the new features of this Lemp patent on which defendant bases any argument against the Harmatta patent. It is on Lemp's diagrammatic showing of an *old* process, in Figs. 1 and 2, that defendant relies. These figures illustrate two ways, described generally by Lemp, for welding two metal strips together by means of two pairs of roller electrodes D, D^1 and D^2, D^3, which can be used either to pass the currents longitudinally through the work or transversely between the members of the two pairs of electrodes D, D^2 and D^1, D^3. Lemp points out that neither of these arrangements is satisfactory because in the case in which currents flow longitudinally through the work the heat is created in the work midway between the two pairs of electrodes and the work between the electrodes is too cold for welding (p. 2, lines 10-24), and in the other case in which the currents are passed between the two members of the pairs of electrodes the heat created by the current between the first pair is lost before the work reaches the second pair of electrodes (p. 2, lines 25-40) and hence the process is ineffective.

Lemp himself, called by the plaintiff as a witness, further explained these old processes (Vol. I, p. 265):—

> "*Q.* 5. Referring now to Figs. 1 and 2 of that patent, which according to the specification illustrates an apparatus that might be used for welding in a

manner employed previous to your invention, please state what method previously employed is therein referred to and illustrated in these Figures Nos. 1 and 2.

A. The apparatus illustrated in Fig. 1 may be used for two different methods, the one illustrated in a previous patent by Professor Elihu Thomson for continuously lap welding sheets of steel or iron, and the other one employed by me for the same purpose or for welding strips of metal together, the difference between the two methods being that in the first the current is passed transversely, while in the latter the sheets to be welded are heated by currents passing longitudinally through the parts to be welded together, and being finally united by pressure, but without necessarily a current passing through the joint.

Q. 6. In those previous methods what was the relation of the electrodes to the overlapped sheets?

A. In both of these methods the electrodes would either entirely overlap the strips to be welded or completely overlap one side. These have particular reference to lap welded joints where the edges are covered by the electrodes proper.

Q. 7. When the methods were applied to welding strips, what was the relation of the electrodes to the strips?

A. The electrodes would completely cover the whole width of the strip or exceed it,—overlap it on either side.

Q. 8. In those old methods please state whether the parts welded together were welded over their entire contacting area.

A. Yes, they were.

Q. 9. State whether that is true of not only the old

methods referred to but to the methods embodying your invention and set forth in that patent.

(Objected to by Mr. Cushman that the patent is the best and only evidence of what is set forth in it.)

A. Yes, it covers both the old and the new.

Q. 10. How do you reconcile these facts with the showing of Fig. 2 of your patent?

A. The only way I can explain this discrepancy is an error of the draftsman at the time this illustration was made.

Q. 11. Has the method of your patent No. 553,923 gone into practical use?

A. No, it never went by the experimental stage."

Lemp's invention for which he took his patent consisted in combining the longitudinal flow of currents with the transverse flow of currents, either of which alone he states is inefficient, with the hope of obtaining sufficient heat by their combination. That is, as shown in Fig. 3 for example, a current of one frequency flows longitudinally in the work from D to D^1 and from D^2 to D^3, and a current of different frequency flows transversely through the work as from D^1 to D^3 and D^5 to D^4. *The object is to preheat the work* so that when it arrives at the point between the rollers D^4 to D^5 it will be so hot that the current from D^5 to D^4 will raise it to the welding temperature, and the weld will be made by the rollers D^4, D^5.

So far as this record discloses, Lemp's invention was no better than the prior processes which he condemned, and it never went into use and never made any impression upon the practical art. It is the opposite in all material respects of the practical and enormously commercially valuable spot welding invention of Harmatta.

At most the Lemp patent is no more pertinent than the Thomson roller patent which we have already discussed.

As the Thomson roller lap welding patent does not anticipate or render invalid the Harmatta patent, neither does the Lemp patent. Neither is in any sense an anticipation of Harmatta's invention.

ROBINSON PATENT No. 574,942, JANUARY 12, 1897 (Vol. II, p. 1070).

This patent (Gravell, Vol. I, p. 172) is for a "rail joint" and specifies the welding of a fish plate *provided with projections* to the side of a rail web. No method or apparatus is disclosed for accomplishing this result. Defendant's expert Dyer assumes that the man skilled in the art, if called upon to carry out this process, would apply large electrodes to the backs of the rail web and fish plate respectively, and pass an electric current from one electrode to the other through the fish plate with its projections and through the rail web.

A serious objection to this process is that the projection on the fish plate being small would heat rapidly, while the part of the rail web against which it abutted would heat slowly, because the heat would be conducted away with great rapidity by the metal of the rail web. The projection would probably melt before the rail web reached welding temperature and no weld could be obtained.

The process is merely a species of butt welding, namely an effort to butt weld the end of the projection on the fish plate to the rail web.

The Robinson patent contains no disclosure or suggestion of Harmatta's inventive thoughts, namely:

1. The idea of a weld between two *plane* metal sheets at any place in their meeting faces.

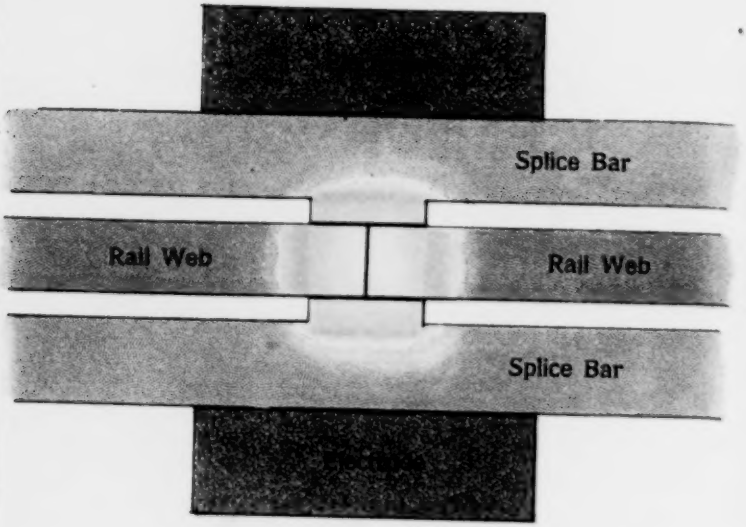
2. The idea of placing the sheets in unlimited and unpredetermined facial contact and of the use of pointed electrodes to concentrate the current in a path through the spot to be welded. In Robinson as in all processes of

butt welding the shape or arrangement of the pieces to be welded provided a path of small cross-sectional area in order to obtain the resistance to the passage of the current necessary to create the welding heat.

3. The idea of a new technique, namely, *a*, heating by a welding current delivered by pointed electrodes to a spot only between the meeting faces of two sheets in extended unlimited facial contact, that spot being entirely surrounded by comparatively cold metal, and *b*, pressing the heated metal to complete the weld without moving the sheets bodily together.

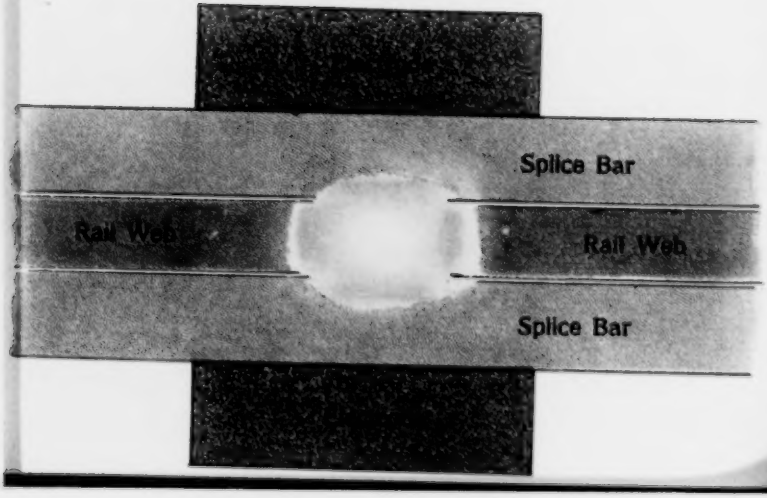
The process of the Robinson patent is therefore absolutely devoid of the characteristics of the process of the Harmatta patent and the Robinson patent contains no suggestion or thought pertinent to the Harmatta invention.

KLEINSCHMIDT PATENT No. 616,436, DECEMBER 20, 1898 (Vol. II, p. 1076).



This patent (Gravell, Vol. I, p. 174) describes another process of welding projections on splice bars to rail webs.

The process is a butt-welding process. As shown in the patent, Fig. 2, for example, the splice bars are provided with projections. At each end of the splice bar is a flat projection of considerable area, and at the middle of the bar is a similar projection extending from top to bottom. Two splice bars equipped with these three projections are placed at the sides of the abutted rails with the middle projections opposite the joint between the rails, and with the projections at the ends of the splice bars opposite to one another and laid adjacent to the rail webs. Electrodes of much greater facial area than the area of the projections are applied against the backs of the splice bars opposite a pair of projections. Each splice bar is in



KLEINSCHMIDT No. 616,436.

PROJECTION WELDING.

HEATING.

PRESSING.

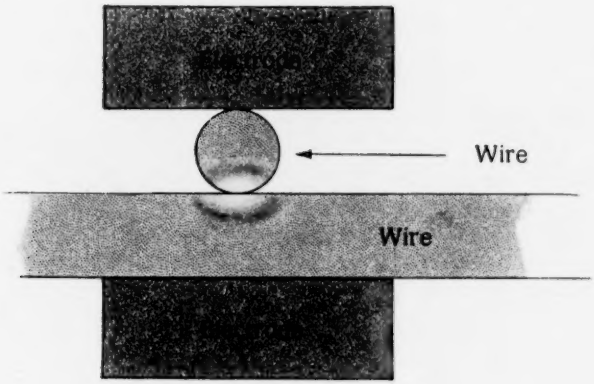
contact with the rail web at the projections only and not at any other point.

In the accompanying drawings we illustrate the Kleinschmidt process.

The first drawing shows the effect of the electric current which passes from one electrode to the other through the splice bars, their projections and the interposed rail-web. The path of the current is determined by the opposing projections on the splice bars. These projections and the portion of the rail-web lying between them are raised to welding temperature, as shown in yellow. The adjacent parts are raised to a lesser temperature by conduction of heat, as shown in red.

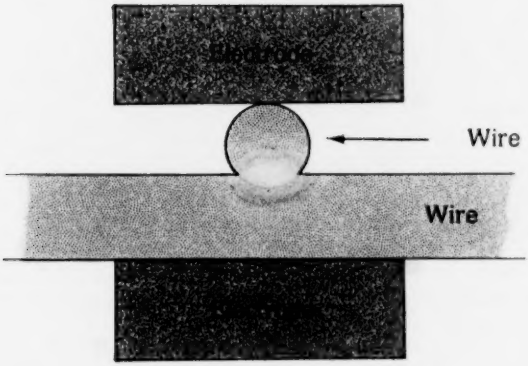
The second drawing illustrates the pressing of the parts together to form the weld. The splice bars are moved bodily against the rail-web and the projections thereon are welded to the rail-web with the usual squashing of the metal and its extrusion, which takes place in all butt welding operations of which this Kleinschmidt process is a species.

The Harmatta patent refers to the Kleinschmidt patent by name and number and says:—



> "I . . . do not wish to be understood as claiming anything disclosed in said patent." (Page 2, lines 94-100.)

There is not in the Kleinschmidt patent the least thought of forming in flat sheets an isolated spot weld. There is not the least idea of placing two plane sheets in unlimited facial contact, nor of the use of tapered electrodes to concentrate or localize the electric current at that spot, nor of delivering the welding pressure to that spot by applying that pressure to yielding metal between the ends of the electrodes, whereby the metal to be welded



PERRY No. 670,808.

CROSS-WIRE WELDING.

HEATING.

PRESSING.

ent and the pressure in a spot surrounded by cold metal, as in the Harmatta patent.

On the application of the welding pressure the parts being welded are moved bodily toward one another and metal is extruded from the welded joint. These operations are the opposites of Harmatta's operations of pressing and moving only the softened metal and not moving the sheets themselves.

The accompanying drawings illustrate the Perry process.

The Perry patent is merely a specific example of a kind of butt-welding. The Perry process is in principle of operation and characteristics the opposite of the Harmatta process. It is absolutely immaterial.

PARKINSON BRITISH PATENT No. 14,536 OF 1894 (Vol. II, p. 1111).

This Parkinson patent (Gravell, Vol. I, p. 183) shows a machine for "*glut-welding*". A wedge-shaped glut piece C^{11} is forged to fit the curved triangular space between the corners of two adjacent triangular-shaped metal spokes F of a wheel. The purpose of the machine is to heat the glut piece and force and spread it into the space between the spokes and weld it to the spokes.

The glut piece C^{11} is pressed into the angle between two spokes by a contact block M. Contact arms L fit into the corners of the spokes in the inside. If a larger wheel is employed the contact arms L are provided with adjustable clamps L^1 to fit the radius of the larger wheel (p. 3, lines 6-9).

As shown in Figs. 1 and 2, the contact arms L are of the same height as the width of the spokes. Also the part of the contact block M which bears against the glut piece is of the same height, as shown in Figs. 4 and 5. By this means the contact blocks or electrodes M and L extend across the entire width of the pieces to be welded

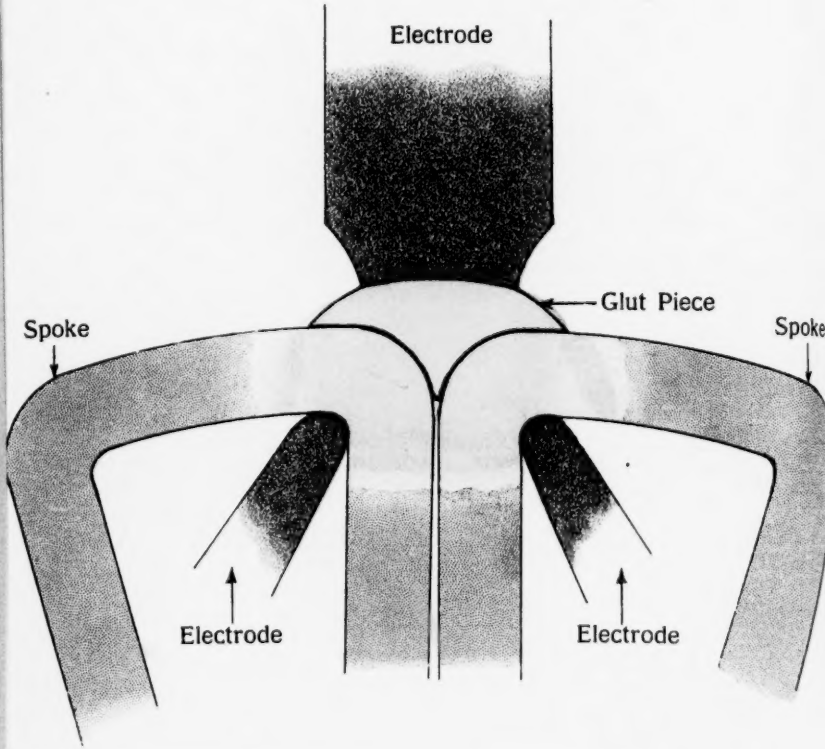
together. This alone is entirely inconsistent with an Harmatta spot weld made *at any point* in the contacting area of two sheets of metal, however remote from their edges.

Parkinson employs an hydraulic ram B to force the contact blocks against the opposite sides of the work. The patent states:

> "The outward movement of the ram B carries forward the contact block M, which makes contact with the glut piece C^{11} and holds it firmly against the outer rim of the wheel C, at the same time bringing the contact arms L against the inner face of the wheel, thereby completing the secondary circuit through the part of the wheel C and glut piece C^{11} to be heated." (Page 3, lines 36-40.)

The heating current is maintained until the entire glut piece is softened. Then another hydraulic ram B^1, upon whose end are fixed two die pieces b, b^1 sliding through recesses in the block B, project these die pieces over the glut piece and spokes, thereby forming a "closed die" around the glut piece and spokes. Finally the full pressure of the ram B is applied and the glut piece is squashed and pressed against the spokes and welded to them over their entire area of contact.

The accompanying drawings illustrate first the heating of the glut piece and adjacent portions of the spokes to welding (yellow) temperature, and second the squashing of the glut piece and its welding to the spokes.

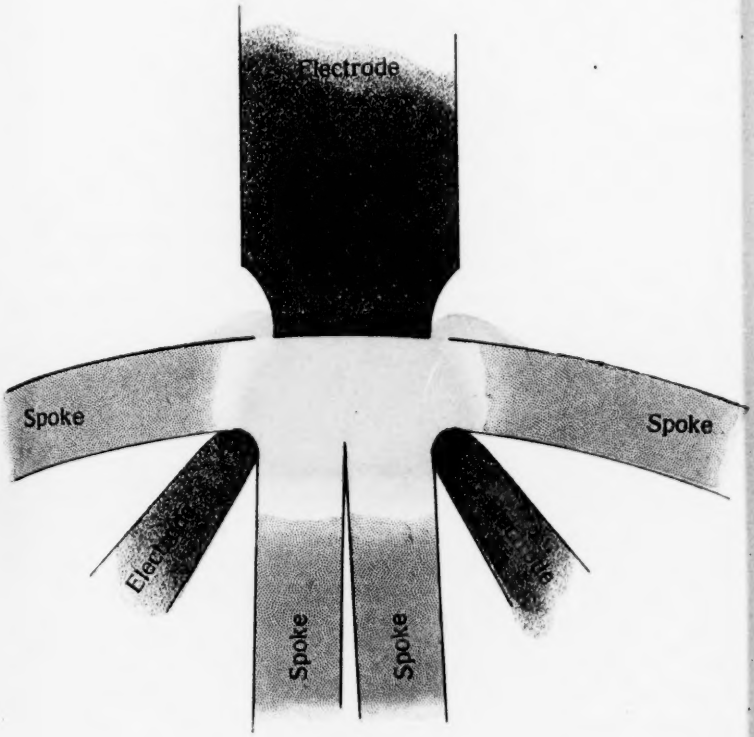


There is no hint or suggestion in the Parkinson patent of making a spot weld, or of any weld, less than the area of the pieces in contact.

There is no suggestion of welding two superimposed sheets of metal together at any spot in their meeting faces, however remote from their edges.

PARKINSON — BRITISH No. 14,536 — 1894.

GLUT WELDING.



HEATING.

PARKINSON — BRITISH No. 14,536 — 1894.

GLUT WELDING.

PRESSING.

In Parkinson the current is not concentrated by the electrodes nor is the pressure for welding concentrated by the electrodes.

The soft welding metal is not surrounded by cold metal and the soft metal is spread during the welding process by the squashing of the glut piece against the spokes.

The glut piece is bodily moved against the spokes while being welded.

It is necessary to shape the glut piece to fit the recess between two adjacent spokes in preparation for the operation.

In all these respects the Parkinson process is the opposite of the Harmatta process.

The Parkinson patent was issued in 1894 and no one was inspired by its disclosure to practice Harmatta's invention of spot welding. The Parkinson patent is in every respect immaterial to the novelty and validity of Harmatta's invention.

The foregoing are all of the patents in the art prior to Harmatta's invention, and all, therefore, that need be considered by the court in determining the novelty and patentability of that invention.

FERRANTI AND RIETZEL.

In addition, the defendant has introduced evidence relating to the Ferranti British patent No. 11,921 of 1903, patented and published in 1904, and to the Rietzel United States patent No. 928,701, issued July 20, 1909, and to certain abandoned and immaterial experiments made by Mr. Rietzel in the year 1898. Although none of these things are to be considered as part of the art prior to Harmatta's invention, the two patents being of later date and Rietzel's work being merely an abandoned experiment, we shall discuss them at this point, because it seems well to answer here certain arguments made by the defendant to the effect that these things affect the novelty and patentability of Harmatta's invention.

FERRANTI BRITISH PATENT No. 11,921 OF 1903 (Vol. III, p. 1479).

The provisional specification of this patent was filed May 25, 1903. The complete specification was filed February 25, 1904, and accepted August 25, 1904.

As the Harmatta patent in suit was applied for December 3, 1903, the Ferranti British patent is not a reference, that is, it is not part of the art prior to Harmatta's invention, for it was not published or patented until after the date of Harmatta's United States application.*

Even if the Ferranti patent were part of the art prior to Harmatta's invention, it would not anticipate that invention or limit the scope of Harmatta's patent (Gravell, Vol. I, p. 318). The Ferranti patent describes a species of butt welding in which the butt end of a turbine blade, crescent-shaped in cross-section, is to be welded to the face of the turbine disc.

Ferranti realized that, as the turbine disc was large and

**Elizabeth* v. *Pavement Co.*, 97 U. S. 126, 130.

massive compared to the turbine blade, its mass would dissipate the heat created in the disc by the welding current so that the disc could not be raised to a welding temperature at the same time as the end of the blade to be welded thereto. He therefore states:—

> "The invention, therefore, consists broadly in adjusting the volume of metal of the disc in the neighborhood of the welding point so that approximately equal heating occurs in both faces to be welded, whereby turbine wheels with welded blades may be reliably produced in an inexpensive way." (Page 1, lines 16-19, Prov. Spec. Vol. III, p. 1479.)

Ferranti therefore modified the face of the turbine disc by cutting grooves crosswise, longitudinally or crisscross or by boring holes therein with the effect of forming small projections on the face of the disc. He also suggests reducing the volume of the turbine disc by boring holes into the edge of the disc.

As he states in both his provisional and complete specifications:

> "The object to be kept in mind in this as in other modifications is to remove sufficient metal to enable the temperature to rise to the welding point as explained above, while at the same time leaving sufficient areas untouched to ensure due mechanical strength in the welded joint." (Page 1, lines 28-31, p. 3, lines 33-36.)

After thus forming projections on the face of the turbine disc Ferranti proposes to butt weld the end of the turbine blade to those projections.

The process is a pure butt welding process, like the Kleinschmidt and Robinson processes already discussed,

in which a metal piece is welded to the projections on another piece. It has none of the characteristics of the Harmatta electrode spot welding process described in the Harmatta patent. The Ferranti welding is in no sense the substitution of a weld for a rivet. *The current and pressure are not concentrated by electrodes* in a spot between the meeting faces of two plane sheets in facial contact, as in the Harmatta process. In the Ferranti process the current and pressure are *concentrated by the work*, namely, the projections on the face of the disc and the turbine blade itself. *The Ferranti welds are made throughout the areas of the parts in contact. The parts move bodily towards one another under the welding pressure and there is extrusion of metal.* The process suggested by the Ferranti patent is therefore not anticipatory in any sense of the process of the Harmatta patent in suit.

The Harmatta patent and a pending United States application by Ferranti filed December 29, 1911, were, wrongfully as we contend, thrown into an interference with one another in the Patent Office because Ferranti in that application has inserted the first four claims of the Harmatta patent in suit. This interference has been decided against Ferranti by all the Patent Office tribunals and by the Court of Appeals of the District of Columbia, 273 Fed. 357.

There can be no interference in fact and none should have been declared. It is only because of the fact that, as is often the case, certain words can more or less inadequately describe two utterly different things, that the Patent Office found a verbal resemblance between Ferranti's butt welding idea and the spot welding of Harmatta.

In this interference Ferranti claimed the right to date his invention from the date of the provisional specification of his British patent.

This claim was made under the provisions of the second paragraph of Section 4887 of the Revised Statutes.*

Inasmuch, however, as Ferranti's United States application in interference (Vol. II, p. 1321) with the Harmatta patent is an application for a patent on spot welding, and as his application for his British patent was an application for an invention relating to the welding of turbine blades to the turbine wheel or disc, and consisted in adjusting of the metal of the turbine disc at the place of welding so that equal heating of the turbine disc at that place and of the end of the blade would result, the applications were for different inventions and not for the same invention, and hence Ferranti's United States application in interference is not entitled to the date of his application for the British patent. Consequently, as Ferranti has no other date prior to the date of Harmatta's United States application, the claim that he is an inventor prior in date to Harmatta must fail.

"An application for patent for an invention or discovery or for a design filed in this country by any person who has previously regularly filed an application for a patent for the same invention, discovery, or design in a foreign country which, by treaty, convention, or law, affords similar privileges to citizens of the United States shall have the same force and effect as the same application would have if filed in this country on the date on which the application for patent for the same invention, discovery, or design was first filed in such foreign country, provided the application in this country is filed within twelve months in cases within the provisions of section forty-eight hundred and eighty-six of the Revised Statutes, and within four months in cases of designs, from the earliest date on which any such foreign application was filed."

A "patent for the same invention", the very phrase employed in Section 4887 before the amendment of 1897, has invariably been construed by the courts as a patent which by claim or otherwise sought to cover the invention *claimed* in the United States patent.

Leeds v. *Victor*, 213 U. S. 301.
Fireball v. *Commercial*, 239 U. S. 156;
Westinghouse v. *Stanley*, 138 Fed. 823.
Acme v. *Commercial*, 192 Fed. 321, 327, 328.

Moreover Ferranti is not the prior inventor of the subject-matter of the claims of the Harmatta patent in suit because his British provisional specification (Vol. III, p. 1479) does not describe anything like spot welding.

To adjust the metal of the disc to obtain equal heating Ferranti suggests the cutting of grooves or holes in the face of the turbine disc which would leave projections to be welded to the butt end of the turbine blade. These projections, rendered plastic by the heat developed by the welding current, would be squashed down by the welding pressure and the spreading metal would fill the spaces between the projections and form one continuous weld (Gravell, Vol. I, p. 353).

If the projections did not merge, the process would be simply that of the prior Kleinschmidt and Robinson patents above discussed, namely projection welding.

Ferranti's process therefore does not anticipate Harmatta's invention.

The Examiner of Interferences in the *Ferranti* v. *Harmatta* interference awarded priority to Harmatta on two grounds, *first* that Ferranti's British provisional specification did not disclose the subject-matter of the interference issues, the first four claims of the Harmatta patent, and *second* that Ferranti, because of his delay, was estopped from making the claims, citing *Wintroath* v. *Chapman*, 248 O. G. 1003, and other cases to the same effect.

The Board of Examiners-in-Chief affirmed this award, holding that Ferranti had disclosed the subject-matter of the claims, but was estopped from making them.

The Commissioner of Patents on appeal by Ferranti held that Ferranti's British provisional specification did not disclose the invention.

The Court of Appeals of the District of Columbia held that Ferranti because of his delay was estopped from making the claims 273 Fed. 357.

That interference is significant as showing that the defendant and its associates have been struggling vigorously for several years to take from Harmatta his first four claims and to obtain a patent containing those claims for themselves.

The Ferranti application in interference with the Harmatta patent has been assigned from Ferranti to Mr. Melville Church, defendant's attorney, and assigned by him to Mulligan, Trustee, who is the head of the Welding Patents' Investigating Committee, an association formed to oppose the Harmatta patent. It is giving its assistance, other than financial, to the defense in this case.

The defendant, the Ford Motor Company, has taken a license from Mr. Mulligan under this Ferranti application (Vol. III, p. 1980).

The efforts that the defendant's associates are making to obtain for themselves the first four claims of the Harmatta patent are very significant as showing their belief that the subject-matter of those four claims is a patentable invention.

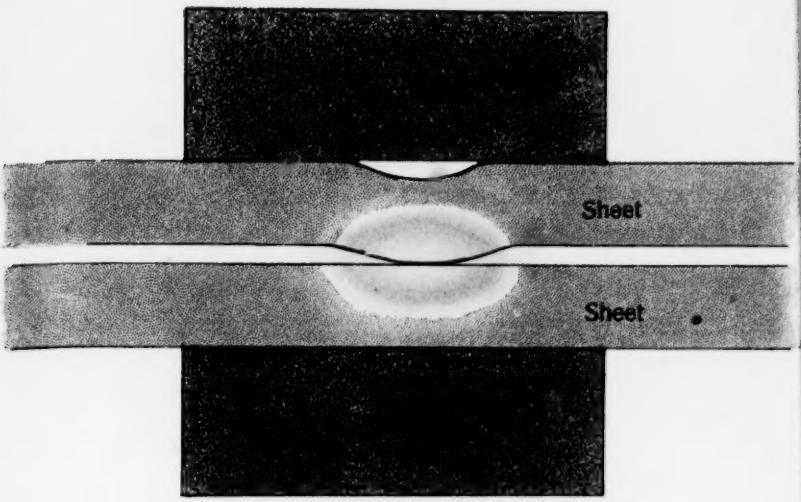
RIETZEL PATENT No. 928,701, JULY 20, 1909 (Vol. II, p. 1098) AND RIETZEL'S EARLY ABANDONED EXPERIMENTS.

The Rietzel patent No. 928,701, issued July 20, 1909, on an application filed February 24, 1905, and the abandoned experimental work done by Rietzel many years before, namely in 1898, are absolutely immaterial and have no bearing whatever upon the validity or scope of the Harmatta patent in suit.

The Rietzel patent both as to its date of issue, July 20, 1909, and its date of application, February 24, 1905, is later than the date, December 3, 1903, when Harmatta filed his application for the patent in suit in the United States Patent Office. It is therefore not part of the art prior to Harmatta and has no effect either anticipatory or

limiting upon Harmatta's patent. It can play no part in this case except to accentuate the fact that Rietzel's work was not on Harmatta's line, but only on that form of butt welding known as "projection welding".

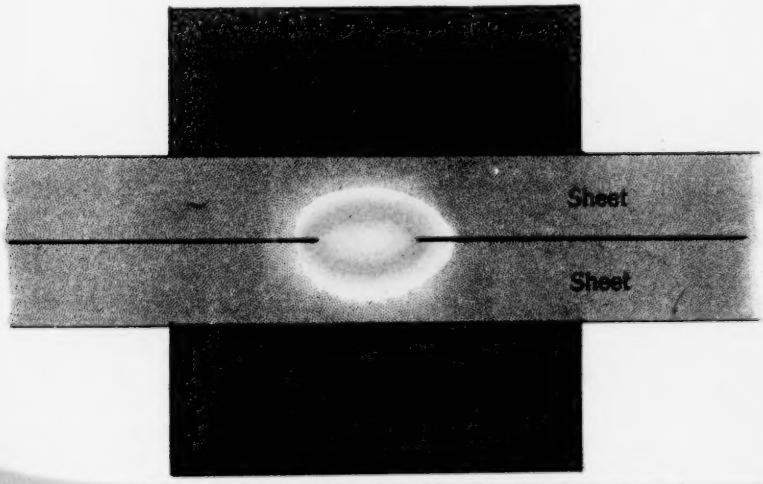
The accompanying drawings illustrate a typical form of the Rietzel process of welding a projection on one sheet (the projection being formed by indenting the back of the sheet) to the face of another sheet. Figs. 2 to 5 of the patent show other forms of projections.



Mr. Rietzel, called by the defendant (Vol. I, p. 633), has fully set forth the nature of certain slight experimental work done by him in *1898*. He states that at that time he was the superintendent of the factory of the Thomson Electric Welding Company and one of the things which he wanted to weld was the ends of wheel or brake bands. The difficulty was that when the ends were butt-welded there was considerable extrusion of metal, or "burr" as it is called, which it was necessary to remove at considerable expense (Vol. I, p. 655). He thought that if the ends were overlapped they could be welded together. He first tried to do this with electrodes extending across the entire width of the ends of the bands, but this operation was not successful as it required too much current. He then took an electrode that had been used for welding studs on another machine and made four or five welds at the edges of the overlapped ends of the wheel band. Rietzel had no idea of making a weld at any point between the meeting faces of two plane sheets of metal in extended contact. He was trying to weld the overlapping edges only of two metal pieces.

Rietzel made a sketch (Vol. III, p. 2041) of what he did. From this sketch it will be seen that he did not at all have in mind Harmatta's process because the overlap of the ends of the bands was less than the width of the electrodes (just as in the Thomson roller process which we have fully dis-

REITZEL No. 928,701.



PROJECTION WELDING.

HEATING.

The above illustrate the process of Fig. 1 of the Rietzel patent. Fig. 2 shows like projections on both sheets in contact with one another. Fig. 3 shows projections cast on one of the sheets. Fig. 4 shows projections cast on both sheets and Fig. 5 shows small pieces of metal interposed between the sheets. All are variants of butt welding.

PRESSING.

cussed), so that the current and pressure were both localized by the arrangement of the work, not solely by the electrodes as in the Harmatta process. There was no creating of welding temperature at a spot in the meeting faces of plane sheets, which spot was entirely surrounded by metal, and no application of pressure to that spot through yielding metal entirely surrounded by a sheath of cold unyielding metal as in the Harmatta process. Rietzel's pressure squashed down the edges of his bands and the squashed metal spread out at the sides. In fact, it was his object to bring the ends of the two bands into one plane (Vol. I, p. 658, X-Q. 158).

Rietzel's welding failed to accomplish his purpose because it did not bring the ends of the bands fully into the same plane which was what he has trying to do. After trying this experiment a few times in July, 1898, he threw the pieces into the scrap heap (X-Q. 159) and abandoned the whole proposition. The only persons who, he thinks, saw this experiment were Mr. Robert W. Clark and Mr. George Osgood, both employees of the Thomson Electric Welding Company (Q. 19). He never communicated his work to the officials of that company (X-Q. 153). Mr. Clark remembers nothing whatever about it. Mr. Osgood has had a stroke of apoplexy and is unable to testify (Clark, Vol. I, p. 254).

This work was merely an experiment and immediately abandoned as it failed to accomplish the purpose desired.

Later in the same year 1898, Mr. Rietzel tried without success to weld together two pieces of a ploughshare by the same method (X-Q. 160). At about the same time he says that he welded two pieces of a ploughshare by punching up projections on one piece and welding them to the other piece. He only made one sample of this work. His statement that later two other samples were made in his absence from the plant is merely hearsay. Mr. Clark,

who, Mr. Rietzel said, did that work, does not recall anything about it (Vol. I, p. 254). This work was also purely experimental and nothing more was done along these lines for several years.

It is not conceivable that if Rietzel had accomplished anything substantial he would not then have developed it further. But *six years elapsed* before Reitzel again did any work involving the welding together of sheet metal pieces at isolated spots. Then in June, 1904, he welded together two sheaves forming a pulley by means of the projection welding method disclosed in his patent No. 928,701 (X-Q. 162), which is not Harmatta's process. As this date is subsequent to Harmatta's date of application this welding is not part of the art prior to Harmatta.

Under these circumstances Rietzel's experiments of 1898 made privately for his own instruction and edification, and not disclosed to any of the officials of the Thomson Company (Rietzel, Vol. I, p. 657, X-Q. 151), which were in no sense commercial, and not further developed or made the basis of any further development along the same lines, and the results of which went into the scrap heap, were merely abandoned experiments and have no effect to anticipate or limit the invention of the Harmatta patent in suit.

The law on this point is thoroughly settled. We cite the authorities, *infra*, p. 208, in connection with our discussion of the alleged McBerty prior use defense.

Defendant contends that in some way, not intelligibly defined, the plaintiff is estopped to deny that Rietzel anticipated Harmatta.

We show later (p. 220) that there is no basis whatever for this contention.

SUMMARY OF THE PRIOR ART.

In the prior art there is no patent which describes or foreshadows the Harmatta process of laying two plane sheets of metal one upon the other and uniting them by a weld at any point in their contacting surfaces however remote from their edges, the weld answering perfectly the purposes of a rivet (Gravell, Vol. I, p. 186, Dyer, Vol. I, p. 592, X-Q. 110).

Only the following patents of the prior art describe the overlapping of two plane sheets: Benardos United States patent 363,320, the Benardos German patent 50,909, Thomson soldering patent 496,019, Thomson riveting patent 396,015, none of which describe electric welding, and Thomson roller patent 444,928 and Lemp patent 553,923.

Of these patents the United States Benardos patent is for arc welding (*supra*, p. 23), the German Benardos patent is for welding or soldering by heating the backs of the sheets by hot blocks, with the same effect as if the heat were applied by a plumber's torch (*supra*, p. 24). The Thomson patent 496,019 is for soldering (*supra*, p. 27), and the Thomson patent 396,015 is for riveting (*supra*, p. 35). In the Thomson patent 444,928 the sheets are overlapped at their edges only, and a lapjoint weld is made by roller electrodes (*supra*, p. 50). In the Lemp patent 553,923 the same weld is made as in the Thomson patent 444,928 and several pairs of electrodes are employed to preheat the work (*supra*, p. 46).

None of the processes of these prior patents were put into use before the date, December 3, 1903, of Harmatta's application for the patent in suit.

None of these patents contain or suggest Harmatta's idea of making a spot weld between two plane sheets of metal.

The other patents of the prior art do not even deal with plane sheets.

The Coffin patent (*supra*, p. 26) and the Thomson patents 347,140 and 347,141 (*supra*, p. 6) describe the butt-welding of the ends of two rods.

The Blanchard patent describes merely the heating of a rivet (*supra*, p. 31).

The Lemp patent 531,197 describes the heating and annealing of a portion of a single hardened steel plate (*supra*, p. 32).

The Burton patent describes merely the heating of the ends of pieces of metal by the electric current, which ends are later welded on the blacksmith's anvil (*supra*, p. 32).

The Robinson patent (*supra*, p. 57) and Kleinschmidt patent (*supra*, p. 58) describe processes for welding projections on heavy plates to other plates, the projection in all cases extending to the edge of the plates. These processes are merely variations of butt welding.

The same is true of the Ferranti provisional specification accompanying his application for his British patent, so that that specification is immaterial even if considered a part of the prior art (*supra*, p. 64).

The Perry patent describes the process for welding cross-wires or superimposed balls and does not deal with sheets. It is butt welding (*supra*, p. 60).

The Parkinson British patent describes the process of squashing and welding a glut piece into a recess between two adjacent spokes of a wheel (*supra*, p. 61).

Harmatta's invention involved the idea of a new result, namely, a weld, perfectly answering the purposes of a rivet, made at any point between the contacting surfaces of two plane sheets of metal however remote from their edges. No prior patent describes or in any way foreshadows a process producing that result. (See Gravell's Chart, Vol. I, p. 427.)

No prior process made between two plane sheets of metal a

weld entirely surrounded by and integral with the metal of the sheets.

No prior process consisted in the following steps (*a*), laying two plane sheets one on the other in unlimited and unpredetermined extent of facial contact, (*b*), concentrating or localizing the welding current in a narrow path in the continuous metal of such sheets to heat only the metal in that path to a soft and plastic condition, leaving the surrounding metal cold and unyielding, and (*c*), applying welding pressure only to that soft and plastic metal to make the weld without moving the sheets bodily and without the extrusion of metal. That process was absolutely new with Harmatta. In that process three steps were absolutely new with him, namely, that of superimposing one sheet on another in indiscriminate unlimited unpredetermined facial contact, that of concentrating or localizing the welding current at a particular spot in the contacting surfaces of two such superimposed plane sheets, and that of localizing the pressure so as to press and move only softened metal surrounded by and integral with unyielding immovable metal.

The Harmatta process is an "*electric welding*" process, that broad art having been created by the original Thomson patents of 1886, wherein the heat is created by the resistance of the work itself. It is a branch of that art which was absolutely new with Harmatta.

Both the Harmatta process and the Harmatta product were radically new.

OPINION OF THE COURT OF APPEALS FOR THE SIXTH CIRCUIT (Vol. III, p. 2098).

The majority opinion of the Court of Appeals for the Sixth Circuit, delivered by Judge Knappen, Judge Denison dissenting, after a review of some of the patents of the prior art, to which we have above referred, sums up

its conclusion denying patentable quality to Harmatta's invention as follows:—

> "We agree with Judge Dodge* that Harmatta's idea of 'making his electric welds small in area rather than large in comparison with the areas of the opposed surface to be joined and isolating them, so as to leave each surrounded by a comparatively large area of unwelded surface', does not involve invention in view of the prior art. In other words, given the desire for a welding in spots, naturally enough suggested by the prior art and by its commercial development, we think Harmatta's specific application of the principles of that prior art involved only the skill of the expert mechanic. Not only every principle, but every electric and mechanical process, involved in the Harmatta claims, was well known in the prior or directly analogous arts, or in mechanical arts generally. We can not think, in view of the prior art, that invention is to be found in the considerations, separately or collectively, that in Harmatta no bodily movement of the sheets is required, that the current is localized and pressure exerted solely by the electrodes, or by the difference in the form of the electrodes, or by the difference in amount of extruded metal, as compared with some of the earlier applications of resistance welding. Although invention is not necessarily negatived by the fact that each element of the combination is old, the question of fact whether the combination itself involves invention in view of the prior art is always present."

The extract from the opinon of Judge Dodge above

*Judge Dodge in the Barney & Berry case in the Massachusetts District Court held the Harmatta patent invalid for lack of patentable invention. 227 Fed. 428, 433.

quoted would make it appear as if Harmatta's idea or inventive thought was merely to change the size of the welds between two opposed surfaces and to isolate those welds, but, we respectfully submit, Harmatta's invention involved much more than this.

What we believe to be the error of the majority of the Court of Appeals is made clear by a further examination of its opinion.

That opinion in the above quoted extract proceeds to explain the reasons why the court thought that no patentable invention was made by Harmatta "in view of the prior art", stating as the basis of its argument that "given the desire for a welding in spots, naturally enough suggested by the prior art and by its commercial development", no invention was required to do what Harmatta did. *If by this the Court meant that before Harmatta the patented art had disclosed or suggested the idea of a weld between the opposing surfaces of two plane sheets of metal at any place in their meeting surfaces however remote from their edges or that such a weld was known in the prior commercial art, we respectfully submit that the Court erred.*

The "desire" for a weld that would perfectly answer the purpose of a rivet (which was generally used), was undoubtedly present and pressing for the many years during which articles have been made from relatively thin metal sheets securely united to each other by rivets.

It is well said that "necessity is the mother of invention" and unsatisfied "desire" to accomplish a certain result is the best known proof of patentable quality in that development of the art which secures that result.

Inventors previous to Harmatta had suggested electric welding in place of ordinary or blacksmith welding for use in many special situations. But to unite two plane sheets *at any point in their meeting faces* required a departure from

known methods beyond "the skill of the expert mechanic" to which the Court of Appeals above refers.

Blacksmith welding of spots in the meeting faces of plane sheets was impracticable, if not impossible, because of the difficulties of heating and pressing the spot as we have explained (*supra*, p. 42). The "desire" for a spot weld had never been satisfied or capable of satisfaction by the blacksmith welding art. The electrical welding art, which for some work, had before Harmatta, taken the place of the methods of the blacksmith, suggested no method of solving the problem of heating and pressing at such a spot, which had so completely baffled the blacksmith.

The technical difficulties involved in creating the heat in the spot to be welded and in completing the weld remained unsolved until Harmatta. No one knew how to develop the heat at the place or spot to be welded when the sheets were in extended undetermined facial contact. No one knew how to apply the pressure necessary for welding without moving the sheets bodily towards one another. No one knew how to dispose of the extruded metal which was the characteristic of all welding before Harmatta.

The Court of Appeals seems to have altogether overlooked these considerations which in so many cases have been held by the courts to be in and of themselves quite sufficient to show patentable quality in an invention (*infra*, p. 98).

The best proof that there was invention in making a spot weld as described in the Harmatta patent is that the "desire", although existing and pressing for such a weld, did not lead even to a "suggestion" either of such a weld or of a method which would produce such a weld. The reason for such lack of suggestion may well have been that, as Harmatta has now shown, such a weld involved

a radical departure from previous theories of welding both blacksmith and electrical. But whatever the reason the lack of such suggestion stands out clearly from a review of the prior art and is of the utmost significance as showing the necessity of "invention" before the Harmatta result could be attained.

The patents referred to in the opinion of the Court of Appeals certainly do not disclose or suggest Harmatta's ideas.

The Thomson basic patents No. 347,140 and 347,141 disclose and suggest only electric butt welding the ends of rods (*supra*, p. 6).

The Thomson patent No. 396,015 for electric riveting is for almost the exact opposite of the idea, result and mode of operation of Harmatta's invention because it necessarily involves the use of a rivet while Harmatta's invention had as its basic thought the idea of a weld to take the place of a rivet and thereby dispense with a rivet. So far as any welding together of the plates around the rivet is concerned the Thomson patent does not describe a process of electric or resistance welding at all because the heat in the plates is *conducted thereinto from the rivet* and there is no suggestion in the patent of obtaining heat by the resistance method. Even if there were such a suggestion it would be immaterial because there is no idea of a Harmatta spot weld and no method disclosed by which one could be made (*supra*, p. 35).

The Thomson patent No. 444,928 for the roller lap welding process (*supra*, p. 40) contains no idea of a spot weld made anywhere between the meeting surfaces of two plane sheets placed on one another in any way. The Thomson process is capable of welding only the limited overlap of the edges of two sheets. Such lap welding was old before Thomson and he adopted an electric roller welding process to get that old result. Such a weld is

not a spot weld in any sense. Before Harmatta such a weld had never been made by anyone by any process of welding.

The opinion of the Court quotes from the Thomson roller patent "the work being properly arranged, so that the pressure devices will press the surfaces to be welded together and simultaneously passing the electric current through the work *at the point of pressure*" (Italics in opinion of Court), as if this was an anticipation or suggestion of Harmatta's invention. The language quoted from the Thomson patent is descriptive of every kind of electric welding known since Thomson's basic patents of 1886 in which this language might well have been employed. In all electric welding the pressure and the current are applied at the same point. Harmatta, like every other electric welder, did this precise thing, but he did it in a way which was entirely different from the way that anybody else had done it before and under new conditions to obtain a new result, which conditions and result were the creations of his own imagination, namely the placing of two plane sheets one on the other in unlimited, unpredetermined facial contact and the making of a spot weld at any point in their meeting faces. The Thomson roller patent nowhere suggests the idea of such indiscriminate placing of the sheets or of any method of welding, *i. e.*, heating and pressing, that could be used with sheets so placed. Thomson could weld only at the overlap of the sheets, with resulting modes of operation which were discarded by Harmatta, who employed radically new and different modes of operation.

The Thomson soldering patent No. 496,019, as we have above explained (*supra*, p. 27), is devoid of any suggestion of Harmatta's inventive thoughts. That patent discloses the idea of heating the contacting pieces, preferably with the aid of heat developed in the electrodes themselves, to

melt the solder over an indiscriminately large area between the pieces. In some examples it describes the use of roller electrodes with corrugated or grooved peripheries, the specification stating as quoted by the Court of Appeals:

> "the rollers exert pressure while the current heats the thin metal pieces at successive points between the rollers".

But there is no justification for the Court's inference herefrom that "this was, to say the least, electric resistance spot soldering".

If the Court means by this that there was "spot soldering", namely isolated spots of solder between the sheets opposite the projections on the rollers, we respectfully submit that there is not only no description or suggestion of this in the Thomson patent, but that such a result would be an impossibility. The Thomson patent points out (p. 2, lines 35-61) that the object of corrugating the electrodes is to increase their resistance where they contact with the work and thereby increase the heat generated in the electrodes themselves at those contact points, which heat is imparted by *conduction* to the sheets. Necessarily the heat of the sheets melts the solder at all points between the sheets reached by the heat of the sheets and there would therefor be a large area, not a series of spots of melted solder. Certainly the area of melted solder would extend throughout the length and breadth of the overlap of the sheets. No "spot soldering" or soldering in spots could possibly result. None is described in the patent.

The very fact that Thomson sought to unite metal pieces by soldering by means of heat created by the resistance to the passage of an electric current, which as compared to welding is a most ineffective weak way of joining two metal pieces together, shows that that inventor, one of the greatest in the history of electrical science, had

no conception that his idea of soldering involved or would suggest to anyone the idea of spot welding which would result in a really effective autogenous union at any point between the meeting faces of two plane sheets. Thomson, great inventor as he was, never took the mental leap from electric soldering to spot welding between plane sheets.

The idea of making a spot weld by the Harmatta process is simply not be to found in this Thomson soldering patent.

The Robinson patent No. 574,942 and the Kleinschmidt patent No. 616,436, also demonstrate that no one at their respective dates of invention, 1894 and 1898, had thought it possible or conceived the idea of uniting two *plane* sheets together by a spot weld. Both Robinson and Kleinschmidt prepared their work by making projections on the surfaces of the plates or bars involved and they merely welded the ends of those projections to the other pieces. This is a species of butt welding. Why should anyone go to the trouble and expense of creating projections, if it was obvious that two plane sheets might and could be welded together at any point in their meeting surfaces? The fact is that no one before Harmatta thought of doing that or thought of any way by which that could be done.

The only "commercial development" of electric welding in any form that appears by this record to have taken place prior to Harmatta's date of invention, which is that of the filing of his application, December 3, 1903, was that of butt welding the ends of rods, etc., according to the Thomson basic patents and a limited use of the Kleinschmidt process which was another species of butt welding. Neither of these commercial practices suggested the idea of a spot weld uniting two plane sheets of metal or suggested any method by which such a weld could be made.

The record fails to show any commercial use, prior to Harmatta, of Thomson's "electric riveting" or of his "electric soldering" or of his roller "lap-welding" or of Robinson's form of "projection welding".

The majority of the Court of Appeals for the Sixth Circuit therefore erred in assuming as a "given" premise for their conclusion that Harmatta's invention was not patentable, that "the desire for a welding in spots" was "naturally enough suggested by the prior art and by its commercial development".

The majority opinion of the Court of Appeals continues and says that—

> "not only every principle but every electric and mechanical process involved in the Harmatta claims was well known in the prior or directly analogous arts or mechanical arts generally".

We respectfully submit that the Court erred in this statement. Where can one find in the prior art the "principle" involved in spot welding? Where is there suggested the possibility of welding together at a spot two plane sheets placed indiscriminately on top of one another? Every prior inventor in the welding art was obliged to prearrange or preshape his pieces to be welded as a necessary preliminary to making the weld and he did so because he had no idea of how otherwise to provide the necessary resistance to the passage of the current and because he had no other idea than that of uniting them over their entire area of contact which was butt welding. Harmatta's "principle" of dispensing with any prearrangement or preshaping of the work was absolutely new in the welding art, electric or otherwise.

His "principle" of imposing the function of concentrating or localizing the current in a spot between two such indiscriminately superimposed sheets solely on the tapered

electrodes was also absolutely new. No one before Harmatta had confined an electric current to the place to be welded, whatever its extent, solely by the shape and relative position of the electrodes themselves. Every prior inventor in that art had proceeded upon the opposite principle of prearranging or shaping the pieces to be welded whereby their parts in contact provided a path of comparatively small cross-sectional area which increased the resistance of those parts so as to generate the heat necessary for welding.

Where in any patent of the prior art is Harmatta's "principle" of applying pressure to be found? Every inventor in the prior art had welded two articles together by pressing them bodily towards one another. Harmatta dealt with a condition of sheets in extended facial contact in which such mutual bodily movement was impossible and no one before him had disclosed or suggested how to deal with such a condition. Harmatta dealt with it by applying pressure solely to the softened metal lying in the path between the two electrodes and utilized the cold unyielding surrounding metal to confine that spot of softened metal so that a very slight movement of the electrodes made the weld. That was an absolutely new "principle" of operation in electric welding. No such principle was of course involved in electric soldering because in that process no welding pressure is employed or is needed, the parts being simply held in position after the current is turned off and the solder cools.

We therefore respectfully submit that every "principle" of the Harmatta process, apart from the basic "principle" of electric welding common to all processes of that art, was new with him and involved patentable quality.

The majority opinion of the Court of Appeals for the Sixth Circuit then states that they find no invention

"separately or collectively" in certain recited characteristics of the Harmatta process.

A mere listing of those characteristics without an appreciation of their relation to Harmatta's new idea and to the problem involved of making a spot weld does not show their true significance. Harmatta after having had the new and radical thought of making a weld at any place in the meeting faces of two plane sheets of metal was confronted with the problem of how to do it. He solved that problem by the invention of new "principles" of operation. Those new "principles" involved radical departures from all previously known methods of operation and give additional and complete patentable quality to Harmatta's basic brilliant thought of making a spot weld by giving to the world a simple commercial new process for obtaining a new result, namely the new product, spot welded articles produced by that process.

Harmatta's invention is a striking example of the truth of the statement of this Court in the case of *Smith* v. *Nichols*, 21 Wall. 112, in which Justice Swayne said (p. 118):—

> "A patentable invention is a mental result. It must be new and shown to be of practical utility. Everything within the domain of the conception belongs to him who conceived it. The machine, process, or product is but its material reflex and embodiment. A new idea may be ingrafted upon an old invention, be distinct from the conception which preceded it, and be an improvement. In such case it is patentable. The prior patentee cannot use it without the consent of the improver, and the latter cannot use the original invention without the consent of the former."

THE HISTORY OF THE COMMERCIAL ART SHOWS INVENTION BY HARMATTA.

The Thomson patents of 1886 protected the business of the Thomson Company, for they covered broadly the process and product of electric welding, as Thomson's invention was a true pioneer invention, having created the art of electric welding. The Thomson patents were sustained in the suit of the *Thomson Electric Welding Company* v. *Two Rivers Manufacturing Company*, 63 Fed. 120, on a motion for preliminary injunction.

But the underlying Thomson patents disclose, as his only specific application of his fundamental invention, one which was of limited utility, namely, the electric welding of the butt ends of two rods. Naturally the Thomson Company was eager to extend its business of electric welding to other fields in which Prof. Thomson's generic idea could be made useful. But until Harmatta's invention, by which for the first time in the art it was practical and feasible by the use of new principles of operation to unite two thin plane sheets of metal together by electric welding *at any spot* or at several spots of their contacting surfaces, no practical application of Thomson's invention of electric welding was made beyond that of the butt welding originally disclosed by him in his patents of 1886 and some variants of that butt welding.

Numerous inventors, including Prof. Thomson himself, between 1886 and December, 1903 (the date of Harmatta's application), endeavored to promote the art of electric welding by the invention of a number of methods all based upon Prof. Thomson's butt welding idea and involving characteristics similar to those of butt welding.

The later patents of the electric welding art, which were prior to Harmatta, were attempts to meet the exigencies of welding together pieces of metal of a variety

of shapes and forms by close adherence to the specific butt welding ideas disclosed by Prof. Thomson in his patents of 1886. Except to a moderate extent in the case of the Kleinschmidt patent they were all unsuccessful and made no impression on the art.

Not one of these inventors from 1886 to 1903 suggested the idea of a spot weld or even attempted to deal with *the problem first successfully solved by Harmatta of uniting by welding two plane sheets of thin metal at any spot in their contacting surfaces.*

Each of these prior patents for electric welding was dealing with articles shaped or arranged in some particular way, *i. e.*, ends of butted rods, projections formed on plates or bars, or overlapped edges of sheets. By such shape or arrangement the current was forced through a narrow path in the work itself. There was no comparatively cold surrounding metal to be dealt with, and the movement of the contacting metals bodily towards and into one another in the process of welding was required and permitted, with the consequent extrusion of metal laterally from the welded joint. Each patentee, including Thomson in his original patents, worked on this same principle of obtaining the necessary resistance at the weld by restricting the cross-sectional area of the metal path through which the current passed, modifying that principle only by applying it to articles shaped or arranged in different ways. Harmatta discarded that principle and invented and discovered the new principle of concentrating the electric current in a path in the body of two sheets in extended facial contact by imposing that function of concentrating the current solely on the electrodes.

So far as this record shows, none of the prior electric welding processes, developed since the Thomson butt welding of 1886, ever made any impression upon the commercial arts, except to some extent that of Klein-

schmidt, which was confined to welding projections on splice bars to rail webs, a species of butt welding operation. As a practical matter, the art of electric welding was no more advanced in 1903 than it was at its inception by Thomson in 1886. No new developments had been made and none had gone into commercial use (except that of Kleinschmidt to a limited extent), although everyone engaged in the business of electric welding and skilled in that art, and particularly the Thomson Electric Welding Company, was anxious to extend electric welding to other fields besides that of butt welding. There awaited the inventor of a new application of Thomson's generic process a large reward for such an invention. Yet nobody worked out any practical way of utilizing Thomson's generic process, except by variations of Thomson's specific method of butt welding, all having the characteristics above stated of that process, until Harmatta made the inventon of the patent in suit, which, while an electric welding process, was in all other respects the antithesis of the prior applications of electric welding and operated on new principles.

PROFESSOR WAGNER'S COMPARISON OF HARMATTA'S INVENTION WITH THE PRIOR ART.

The Court will apprehend the radical novelty of Harmatta's invention from the fact that while other inventors in the electric welding art, following Thomson's creation of that art in 1886, merely adapted electric welding to the making of the same kind of welds that had been made before by other welding processes, Harmatta accomplished a new result, namely a spot weld, perfectly answering the purposes of a rivet, made at any point between the contacting faces of two plane sheets of metal where a rivet had formerly been employed, without the necessity of any prearrangement or modification of those sheets, which

weld had never before been made by any process of welding.

Professor Wagner, an eminent physicist and electrical engineer, professor of mechanical and electrical engineering at Rose Polytechnic Institute, Terre Haute, Indiana, has carefully considered the prior art (Vol. I, p. 331, p. 340). He states his conclusions as follows (p. 340):—

> "We come now to a consideration of the Harmatta patent in suit, No. 1,046,066, dated December 3, 1912. *Harmatta undertakes to solve a problem different from those dealt with by prior inventors*, but falling also under the general line of development from the original Thomson electric welding patent. In most of the prior patents which I have considered, inventors were trying to accomplish by electric welding something which had previously been done by a blacksmith using ordinary heating methods. The original Thomson patent proposed to make butt welds of rods and bars, a thing which a blacksmith commonly did. The Thomson roller welding patent also attempted to do by electrical methods what was formerly done in metal working, namely, to make lap weld seams. Kleinschmidt performed a butt welding operation which might have been done in a well equipped forge shop, but which was novel because of necessity the work was required to be done away from a forge shop and required portable apparatus.
>
> "Harmatta, however, attacks a problem which had never been solved by blacksmithing methods. His problem was to fasten together by electric welding flat sheets of metal placed one on top of the other. In the sheet metal art, this had been done previously by the use of rivets. Harmatta replaced rivets by electrically welding the plates at the spots where riveting would ordinarily be used. The method

employed by Harmatta was to place electrodes opposite each other with the plates to be joined lying between the electrodes; one of the electrodes was stationary, the other electrode could be moved toward the stationary electrode and forced toward it with considerable pressure. A suitable electric current was passed through from one electrode to the other and a pressure exerted upon the movable electrode. It was found that the current thus passed through the two plates pressed together would raise the metal to a welding temperature and the pressure would produce a weld.

"In the development of the art of electric welding prior to Harmatta the area of the surfaces in contact between the two pieces to be welded was always limited in extent. In the original Thomson patent the area of the ends of the rods being joined was the contact surface, and determined largely the amount of heat developed. In the Thomson and Lemp roller patents the amount of overlap of the plates restricted the area of contact surface. In the Robinson, Kleinschmidt and de Ferranti patents the size of the projections determined the contact surface, and in all these cases the completed weld was of substantially the same area as the contacting surface.

"*There was, therefore, nothing in the prior art to show Harmatta that when two sheets were placed one upon the other, contacting over a large area, these sheets could be welded together in an isolated spot.* I do not believe that anyone skilled in the art at the time of Harmatta's invention could have stated with any degree of assurance in advance of actual trial that Harmatta's device would produce a real serviceable weld." . . .

"For the reasons given above, it is my opinion that the flow of electricity and of heat in the practice of the

Harmatta process of spot welding is so complex that the teachings of the prior art would not suggest the Harmatta invention, and that with the knowledge and skill available at the date of the Harmatta invention it would not be possible to state whether or not the Harmatta process would be successful in producing commercially valuable welds. As a matter of fact, the Harmatta process of spot welding has proven of immense commercial value, and the fact that the operation seems so simple after it has once been accomplished should add to rather than detract from the merit of the invention. It is the more remarkable in that the fundamental Thomson electric welding patent antedates the Harmatta invention by some seventeen years; and that, while the art was developed in a number of other directions, the development of spot welding waited so long. The reason for this seems to me to be that in the other lines of development of electric welding the attempt was made to accomplish by electric welding what had previously been done by other metallurgical or blacksmithing operations. *Harmatta struck out in a new field and accomplished something which had never before been accomplished by any method, namely, the welding together at isolated spots, and without previous preparation, parallel, superimposed metal sheets.*"

HARMATTA'S PROCESS INTRODUCED INTO THE UNITED STATES IN 1904.

The spot welding process of the Harmatta patent was first introduced into the United States in 1904 directly from Harmatta by the purchase of a license for kitchen ware and like articles by the National Enameling & Stamping Company from the Eisenhutte Silesia Company of Hungary, the owner of Harmatta's rights. The license dated December 3, 1904, is in evidence (Vol. I, p. 433). With the license the National Company purchased two Harmatta spot welding machines which are now in its factory and have been in constant use up to the present time. Since then the National Company has built and used between eighty and one hundred spot welding machines. These facts are established by the testimony of Mr. Knapp, the general director of the National Company (Vol. I, p. 125). Undoubtedly this extensive use of the Harmatta process and the sale of its products by the National Company beginning in 1904 spread the knowledge of Harmatta spot welding throughout the United States.

INFRINGEMENT.

Infringement by the defendant is established by the plaintiff's interrogatories and the defendant's answers thereto (Vol. I, pp. 20-23) and is not denied. Those interrogatories and answers are stipulated to have the same force as a deposition (Vol. I, p. 24).

According to these interrogatories and answers, the defendant, the Ford Motor Company, has been practicing during the period between December 3, 1912, and the filing of the bill of complaint, at its factory in Detroit, the Harmatta spot welding process by means of a number of spot welding machines purchased from the Winfield

Electric Welding Machine Company prior to December 16, 1916.

These machines are correctly represented in the drawing (Vol. I, p. 22, and *supra*, p. 14).

In these machines the copper electrodes are tapered and are connected respectively to the terminals of a secondary circuit of an electric transformer. In operating these machines the operator places two or more superimposed thicknesses of metal constituting the work between the electrodes, presses the electrodes against the work and passed the electric current through the electrodes and through the work at the spot between the electrodes controlling the current by means of a switch. When the weld is completed the current is cut off and the electrodes separated from the work.

The defendant has practiced this process in its manufacture of mufflers, radiators, fenders, bodies and other parts of its automobiles (Vol. I, p. 23).

Plaintiff's Exhibit No. 2, a spot welded part of a muffler, is a fair example of the products produced by the defendant as a result of practicing the Harmatta process (Vol. I, pp. 20, 23).

The plaintiff's expert, Gravell, with reference to the defendant's process and product testified (Vol. I, p. 64):—

> "An example of the product of the process is shown in Exhibit No. 2 illustrating how the process is repeated a number of times on the same article to produce a number of welds.
>
> "The exhibit shows a number of isolated welds, which are technically known as 'spot welds'.
>
> "It is evident that the metal heated for welding has been confined by relatively cold metal and that no extruded metal has occurred. (In one case the metal from the weld has extruded, but this is a defective weld.)

"It is also clear from Exhibit No. 2 that the superimposed thicknesses of metal did not move in relation to each other during the process, for prior to the processing these parts were placed in close overlapping contact and could not possibly move. This is especially clear when we consider that after the first weld was made the two parts were locked together.

"The answers to the interrogatories considered in connection with Exhibits Nos. 1 and 2 clearly describe the same process as is described in Harmatta's specification.

"In both cases pointed electrodes concentrate the current and the pressure which are applied to the superimposed thicknesses of metal which constitute the work, the weld occurs in the work between the electrodes and is restricted to the spot where the current and pressure are concentrated. During the welding process the superimposed parts do not move in relation to each other, the metal heated for welding is confined by relatively cold metal and no extruded metal is produced.

"I know of my own knowledge that the answers to the interrogatories are correct and that the Harmatta process is used at the Detroit plant of the Ford Motor Co., for on January 9, 1918, I visited the Ford plant and saw machines arranged to carry out the Harmatta process shown in Exhibit No. 1, and I personally operated one of these machines and found that it produced a spot weld according to Harmatta's process. The specimen which I welded I here produce."

The defendant has, therefore, practiced the exact Harmatta process set forth in the patent in suit and made by that process the Harmatta product. It has therefore infringed all of the claims of the patent.

Neither in the District Court nor in the Court of Appeals, has the defendant denied infringement.

SUMMARY OF FACTS SO FAR DISCUSSED.

The plaintiff, the Thomson Spot Welder Company, is engaged in the business of manufacturing, selling and leasing electric welding machines by means of which the process described and claimed in the Harmatta patent is carried out and the welded articles to which some of the claims of the Harmatta patent are directed are produced.

The defendant has infringed and makes no attempt to deny its infringement.

The sole question, therefore, is whether the Harmatta patent is valid.

As to this question the record establishes certain fundamental facts:

That the invention, colloquially known as "spot welding", described in the Harmatta patent is based upon the idea of making, and results in *a weld* between two *plane* sheets of metal *indiscriminately superimposed* upon one another in unlimited unpredetermined extent of contact, which weld is made *at any spot* in their meeting surfaces and *which answers perfectly the purpose of a rivet.*

That before December 3, 1903, the date of filing of Harmatta's application, no patent or printed publication disclosed that idea or described a process which produced or purported to produce that result. *Spot welding was absolutely new with Harmatta.*

That Harmatta described and made practical *a new method of manipulating sheets to be welded*, namely the superimposing of two plane sheets *indiscriminately* one upon the other in unlimited unpredetermined extent of facial contact and without any reshaping of those sheets, as by the creation of projections thereon. It was absolutely new with Harmatta to get rid of the requirement, neces-

sarily present in all preceding methods of welding, of any special relative arrangement of the pieces to the welded or of preshaping those pieces.

That Harmatta described new instrumentalities to be used in electric welding, namely tapered electrodes to concentrate the current.

That Harmatta was the first inventor in the art to impose the function of concentrating or localizing the welding current solely on to the electrodes.

That Harmatta discovered a fact, never before known, namely that in two plane sheets in indiscriminate extended facial contact a welding current would be confined by tapered electrodes to the path in the sheets between the ends of those electrodes to heat the spot in that path between the faces of such metal sheets. No one knew that fact before Harmatta's discovery of it. It was not warranted by established electrical theory.

That Harmatta disclosed the fact, previously unknown, that by the use of such electrodes a weld could be made between two such sheets of metal, without moving them bodily towards one another, by pressing on heated metal only, which heated metal was surrounded by cold unyielding metal.

That Harmatta's invention was first introduced commercially into the United States in 1904 by the National Enameling and Stamping Co., as stated (*supra*, p. 92), and has been practiced continuously and successfully since then by Harmatta's licensees and assignees.

That the invention of spot welding described in the Harmatta patent has gone into the most successful commercial use in welding sheet metal articles of every conceivable kind. *Billions of spot welds* are made every year by plaintiff's licensees, and billions are made by infringers.

That Harmatta's invention of spot welding created a branch of the art of electric welding which is of greater commercial utility than that of all other kinds of electric

welding added together (Gravell, Vol. I, p. 63). It has taken a position in the metal working arts of unquestioned industrial pre-eminence.

Under these circumstances the defendant's main contention that Harmatta's invention is lacking in patentable quality must certainly fail.

PATENTABILITY OF THE IDEA OF ELECTRODE SPOT WELDING.

The invention in the Harmatta patent lies fundamentally in Harmatta's strikingly novel idea of the isolated electrode spot weld made from the metal of the plane, flat surfaces of two thin sheets of metal indiscriminately superimposed one on the other, at any spot between them, whereby the sheets are joined together more cheaply and more strongly than they could be joined by a rivet. This idea he carried out by solving a new problem and by devising new principles of operation and a process having new characteristics. He was not merely welding by electricity two things that had been welded before by other means, but he had the new idea of "welding together at isolated spots and without previous preparation, parallel superimposed metal sheets", which was "something which had never before been accomplished by any method" as above stated by Professor Wagner. So different was the problem that Harmatta solved from any that had been dealt with by any one before him that his invention involved principles of operation and characteristics which are exactly the opposites of those of the electric welding processes of the prior art except in so far as they all involve the basic principles of electric welding.

Such a spot weld made between such plane superimposed sheets of metal at any point in their meeting surfaces was an absolutely new result in the art. No one had ever made such a weld before.

Even if each of the steps involved had been old in the art, which is not the case, the fact that Harmatta's invention attained this new result is the best evidence of invention.

In *Loom Company* v. *Higgins*, 105 U. S. 580, this Court in sustaining a patent for a new arrangement of old elements in a loom which raised the output of the loom from 40 to 50 yards per day said (p. 591):—

> "It may be laid down as a general rule, though perhaps not an invariable one, that if a new combination and arrangement of known elements produce a new and beneficial result, never attained before, it is evidence of invention."

This language has been quoted with approval by this Court in *Carnegie Steel Company* v. *Cambria Iron Company*, 185 U. S. 403, 446.

In *Expanded Metal Company* v. *Bradford*, 214 U. S. 366, this Court in sustaining a patent for a new method of making reticulated metal said (p. 381):—

> "It is perfectly well settled that a new combination of elements, old in themselves, but which produce a new and useful result, entitles the inventor to the protection of a patent." Citing *Loom Company* v. *Higgins*, 105 U. S. 580, 591.

The steps of the process by which Harmatta achieved his new result, except insofar as they embodied old principles of electric welding, were absolutely new.

They were, *first* the indiscriminate placing of two flat sheets upon one another without regard to the extent of their facial contact. No one had ever done this before in any kind of welding, blacksmith or electric. The very lack of a predetermined relation between the sheets is a feature of Harmatta's process which gives it not only

novelty but widespread application to all kinds of articles made of sheet metal in which the sheets of necessity can not be placed in a predetermined limited relation as was required by all welding processes of the prior art.

Second, Harmatta's concentration of the welding current to a path in those sheets between the ends of two tapered electrodes was an absolutely new electrical feat involving a new discovery that the welding current would confine itself under those conditions to that path.

Third, the completion of the welding by the slight but firm movement of the electrodes themselves bearing upon softened metal on each side of the spot to be welded without moving the sheets bodily was an absolutely new step in the welding art. No one had ever done that before.

Harmatta's new result was therefore achieved by new series of steps, each one of which was in itself new.

There are many cases in which this court has sustained patents for processes in which there was far less novelty in the several steps constituting those processes.

AUTHORITIES ON PATENTABLE PROCESSES.

This Court has held consistently that a process is patentable when based upon a new idea in the treatment of materials.

In *Mowry* v. *Whitney*, 14 Wall. 620, this Court held valid and infringed a patent for a process of casting car wheels. According to the prior art, a car wheel was cast in a mould, around the periphery of which was a metal rim, whereby the tread of the wheel was chilled quickly, thereby making it hard, while the centre of the wheel cooled slowly, thereby making it tough, but the difficulty was that, due to the unequal rate of cooling, the metal drew away from the centre and often broke. Whitney's improvement consisted in the idea of inserting the car wheel, after the rims had been chilled but before the rest of the wheel had

chilled, into a furnace where the whole wheel was again heated, after which it was allowed to cool slowly.

The court said (p. 642):—

> "The novelty of the patentee's invention is not therefore disproved by evidence that glass, or speculum metal, or even other iron casings had been annealed and slow-cooled, prior to the time when it was made. Of this there is very considerable evidence both in the testimony of witnesses and printed publications. The specification disclaims invention of annealing iron castings done in the ordinary mode. It claims annealing when applied to cast-iron railroad wheels, in the mode or by the process described. It is not therefore merely an old contrivance or process applied to a new object, a case of double use. A new and previously unknown result is obtained, namely, the relief of the plate of the wheels from inherent strain without impairing the chilled tread, a result which, though anxiously sought, had not been obtained before Whitney's invention. We are therefore of opinion that the defence set up that the patent was void for want of novelty of invention is unsustained."

In *Lawther* v. *Hamilton*, 124 U. S. 1, this Court held valid and infringed a patent for the process of extracting oil from cotton seed, the novelty of which consisted in omitting the use of muller-stones which were used in previously employed processes for crushing the seed, and instead crushing the seeds between heavy rollers.

The court said (p. 11):—

> "We cannot but think that Lawther discovered a new process of manufacturing oil from seeds, and that he was entitled to a patent therefor; and we are of the opinion that the patent in suit, construed as we have suggested, is a good and valid patent."

In *Tilghman* v. *Proctor*, 102 U. S. 707, this Court held valid a patent for a process of making glycerine which consisted in manufacturing glycerine from fatty bodies by the action of water at high temperature and pressure.

In *Expanded Metal Co.* v. *Bradford*, 214 U. S. 366, this Court held valid and infringed a patent for making expanded metal sometimes known as "reticulated" metal, which is a metal screen having diamond-shaped openings formed by cutting a metal sheet in slits and then pulling the cut metal so as to open the slits.

Previous to the invention of the patent in suit the metal after being cut had been merely bent, thereby producing irregularities and shortening the sheet crosswise. By the process of the patent in suit the metal sheet was simultaneously cut and stretched to form the diamond-shaped openings.

The court found patentable invention in the improvement, and said (p. 381): —

> "It is suggested that Golding's improvement, while a step forward, is nevertheless only such as a mechanic skilled in the art, with the previous inventions before him, would readily take; and that the invention is devoid of patentable novelty. It is often difficult to determine whether a given improvement is a mere mechanical advance, or the result of the exercise of the creative faculty amounting to a meritorious invention. The fact that the invention seems simple after it is made does not determine the question; if this were the rule many of the beneficial patents would be stricken down. It may be safely said that if those skilled in the mechanical arts are working in a given field and have failed after repeated efforts to discover a certain new and useful improvement, that he who first makes the discovery has done more than make the obvious improvement which would suggest

itself to a mechanic skilled in the art, and is entitled to protection as an inventor. There is nothing in the prior art that suggests the combined operation of the Golding patent in suit. It is perfectly well settled that a new combination of elements, old in themselves, but which produce a new and useful result, entitles the inventor to the protection of a patent. *Loom Company* v. *Higgins*, 105 U. S. 580-591.

"To our minds, Golding's method shows that degree of ingenuity and usefulness which raises it above an improvement obvious to a mechanic skilled in the art, and entitles it to the merit of invention. Others working in the same field had not developed it, and the prior art does not suggest the combination of operations which is the merit of Golding's invention."

In *Carnegie Steel Co.* v. *Cambria Iron Co.*, 185 U.S. 403, this Court held valid and infringed the Jones patent for a method of mixing molten pig-metal, the gist of which consisted in providing a large reservoir into which the molten metal from different furnaces was delivered and from which the molten metal was drawn off to be treated in the converters, there always being enough molten metal in the reservoir to constitute a "dominant pool" so that the variations in the metal coming from the different furnaces were eliminated by the blending of all the metal in the reservoir. The novelty consisted in the idea of this dominant pool, which was never exhausted.

The court, referring to certain prior devices which might have been used to carry out the process of the patent, made the following statement, which is particularly pertinent to the defendant's argument on the prior art in this case (p. 421):—

"This defence presents the common instance of a patent which attracted no attention, and was com-

mercially a failure, being set up as an anticipation of a subsequent patent, which has proved a success, because there appears to be in the mechanism described a possibility of its having been, with some alterations, adaptable to the process thereafter discovered. As hereinafter observed, a process patent can only be anticipated by a similar process. It is not sufficient to show a piece of mechanism by which the process might have been performed."

And again on page 425 the court said:—

"If the mere fact that a prior device might be made effective for the carrying on of a particular process were sufficient to anticipate such process, the absurd result would follow that, if the process consisted merely of manipulation, it would be anticipated by the mere possession of a pair of hands."

On the question of invention as distinguished from mechanical skill the court said (p. 429):—

"It is true the Jones patent is a simple one, and in the light of present experience it seems strange that none of the expert steel makers, who approach so near the consummation of their desires, should have failed to take the final step which was needed to convert their experiments into an assured success. This however, is but the common history of important inventions, the simplicity of which seems to the ordinary observer to preclude the possibility of their involving an exercise of the inventive faculty."

The court concluded its opinion by quoting the law from *Loom Co.* v. *Higgins*, 105 U. S. 580, 591, as follows (p. 446):—

"We cannot better conclude this opinion than by

> the following extract from the opinion of Mr. Justice Bradley in *Loom Co.* v. *Higgins*, 105 U. S. 580, 591: 'But it is plain from the evidence, and from the very fact that it was not sooner adopted and used, that it did not, for years, occur in this light to even the most skillful persons. It may have been under their very eyes, they may almost be said to have stumbled over it; but they certainly failed to see it, to estimate its value, and to bring it into notice. . . . Now that it has succeeded, it may seem very plain to any one that he could have done it as well. This is often the case with inventions of the greatest merit. It may be laid down as a general rule, though perhaps not an invariable one, that if a new combination and arrangement of known elements produce a new and beneficial result, never attained before, it is evidence of invention'."

These cases are fair examples illustrating the rules of law applicable to patentable processes. In each of these cases there was a novel idea, corresponding to Harmatta's novel idea of electrode spot welding. The Harmatta conception of electrode spot welding involved patentable invention as truly as the idea of a dominant pool in steel making, the idea of simultaneously stretching as well as cutting the sheet of metal to form expended metal, the idea of reheating and slowly cooling the car wheels, the idea of eliminating the crushing of the cotton seeds by muller-stones, and the idea of using water at high heat and pressure to extract glycerine from fatty bodies.

In all these processes the invention is in the conception of the treatment to which the material acted upon is subjected and not in the mechanism by which the process is carried out. Just because this is true in the case of a process it is easy to say that this new idea, which seems so

simple now that it is known, did not involve invention, and that the devices of the prior art could be easily modified so as to carry out the process of the patent in suit.

But the answer is that no one before had the necessary and lacking idea, so that, although there existed the latent demand, it was not satisfied until the idea was conceived. This required invention.

In this case the process of electrode spot welding, of which Harmatta undisputably was the first inventor, dealt with and solved a new problem. It involved new principles of operation and new characteristics. It is not described or suggested in the prior art and it produced a new and valuable result, namely, thin sheets of metal united together at any spot on their meeting faces by an electric weld answering all the purposes of a rivet. No one had ever thought of doing this before by any process of welding, electrical or otherwise.

The process has gone into very wide commercial use and has enabled manufacturers of sheet metal articles to make these articles more cheaply and more strongly than they could by riveting them, and also to make a large number of articles which they could not make by riveting because the rivet heads would have marred the appearance of the article and because the union must be made at spots where the shape of the article prevents the use of a rivet.

CASES OF PATENTABLE ARTICLES ANALOGOUS TO THE HARMATTA PRODUCT.

The Harmatta process produced a product which had never before been attained in the art. It consists of two thin metal sheets or plates with their inner contacting or meeting faces welded, so as to form an intimate union, at distinct and separate or isolated points, such isolated welds, which are formed solely from the metal of the sheets or plates, securing them together and practically making them into one integral article.

This product has been embodied in all kinds of articles and proved its thorough usefulness in the commercial world as shown by the uncontradicted testimony of Mr. Cutter (Vol. I, pp. 133-137). Before Harmatta made his invention no such product existed, and no such product is suggested by the prior patents introduced in this case, as we have shown above. The article is a new combination of elements, namely, the two sheets and the isolated spot welds by which they are joined together. It is a new and useful combination which under the authorities is patentable. We cite a few analogous cases from the decisions of this Court:—

Barbed Wire Patent, 143 U. S. 275.

The patent was for a barbed wire fence consisting of two strands of wire twisted together, around one of which was coiled short pieces of wire or barbs held in place by the other strand. The prior art disclosed a barbed wire fence having two strands twisted together, on one of which was strung diamond-shaped prongs of flat metal.

Patentability turned on the question whether there was invention involved in simply using a coil of wire instead of a diamond-shaped piece of flat metal as the barb. The device of the patent had met with success.

The Supreme Court held (p. 282) as follows:—

> "Under such circumstances courts have not been reluctant to sustain a patent to the man who has taken the final step which has turned a failure into a success. In the law of patents it is the last step that wins. It may be strange that, considering the important results obtained by Kelley in his patent, it did not occur to him to substitute a coiled wire in place of the diamond shape prong, but evidently it did not; and to the man to whom it did ought not to be denied the quality of inventor."

Krementz v. *Cottle*, 148 U. S. 556.

The patent was for a collar button made of one piece of metal as compared with the prior art showing collar buttons made out of several pieces of metal soldered together.

The Supreme Court said (p. 559):—

> "It is not easy to draw the line that separates the ordinary skill of a mechanic, versed in his art, from the exercise of patentable invention, and the difficulty is specially great in the mechanic arts, where the successive steps in improvements are numerous, and where the changes and modifications are introduced by practical mechanics. In the present instance, however, we find a new and useful article, with obvious advantages over previous structures of the kind. A button formed from a single sheet of metal, free from sutures, of a convenient shape, and uniting strength and lightness, would seem to come fairly within the meaning of the patent laws."

Diamond Rubber Co. v. *Consolidated Rubber Tire Co. and Rubber Tire Wheel Co.*, 220 U. S. 428, 434.

In this case the patent covered the holding of a solid rubber tire in the U-shaped channel of a wheel by two circumferential wires instead of cementing it in place.

> "The tire has utility, a utility that has secured an almost universal acceptance and employment of it, as will subsequently appear. It was certainly not an exact repetition of the prior art. It attained an end not attained by anything in the prior art, and has been accepted as the termination of the struggle for a completely successful tire. It possesses such amount of change from the prior art as to have received the approval of the Patent Office, and is entitled to the

presumption of invention which attaches to a patent. Its simplicity should not bind us as to its character. Many things, and the patent law abounds in illustrations, seem obvious after they have been done, and, 'in the light of the accomplished result', it is often a matter of wonder how they so long 'eluded the search of the discoverer and set at defiance the speculations of inventive genius' (*Pearl* v. *Ocean Mills et al.*, 11 Off. Gaz. 2). Knowledge after the event is always easy, and problems once solved present no difficulties, indeed may be represented as never having had any, and expert witnesses may be brought forward to show that the new thing which seemed to have eluded the search of the world was always ready at hand and easy to be seen by a merely skillful attention. But the law has other tests of the invention than subtle conjectures of what might have been seen and yet was not. It regards a change as evidence of novelty, the acceptance and utility of change as a further evidence, even as demonstration . . . if he has added a new and valuable article to the world's utilities he is entitled to the rank and protection of an inventor."

THE CLAIMS.

Of the claims of the Harmatta patent it will be sufficient to quote, as typical, claims 3, 8, 12 and 17, which are as follows:—

"3. *The herein described method* of uniting two pieces of metal, consisting in pressing them together while passing a heating electric current from one to the other and *localizing the flow of current* and the heating throughout the operation *in a spot* or spots of circumscribed or limited area as compared with the area of the immediately opposed surfaces so as to limit the union of the pieces to a spot or spots."

"8. The method of electrically welding two plates or sheets of metal together face to face between electrodes, consisting *in restricting the area of contact of an electrode with said plates to a spot*, passing a heating electric current from said electrode to the co-operating electrode through said spot to heat the work to welding temperature and *applying pressure to the work in line with said spot* to effect a welding of one plate to the other."

"12. The method of electrically welding two pieces of sheet metal to one another, consisting in pressing the sheets together by *pressure* applied and *localized* in a distinct well-defined point or spot on the rear surface of a sheet while passing an electric current through them in the line of the pressure, thereby *localizing the path of the heating current* from one to the other of the meeting surfaces of the sheets to cause the said sheets to be heated to welding temperature by the electric resistance of the work at said spot, and *applying pressure localized* over said spot whereby the pieces are welded together at a distinct well defined *spot* in their meeting surfaces *answering the purposes of a rivet.*"

"17. Metal plates fastened together by a number of *distinct or isolated welds on their meeting surfaces* and in spots *comprising meeting portions* of the metal plates, the backs of said plates being practically unaltered in their metallic condition and the spots on the meeting surfaces being separated from one another by distinct unwelded areas."

Each of the method claims of the patent clearly defines the precise process of spot welding described in the specification of the Harmatta patent employing the localizing of the current by pointed electrodes to affect new modes of

electric and thermal operation, and the localizing of the pressure to act upon the spot to be welded which is surrounded by and integral with colder metal.

The product claims of the Harmatta process likewise define the specific spot welded product obtained by the Harmatta process in which the welded spots are formed from the metal of the plane sheets themselves.

Claims 7 to 16 of the Harmatta patent define in limited terms Harmatta's specific process of making spot welds in two plane sheets in facial contact by means of localizing the current and pressure by pointed electrodes.

The process claims, 1 to 6, and the product claims, 17 to 21, are expressed in somewhat broader terms, but in this case it is not necessary for the Court to give them any other or broader construction than as covering the specific process and its product described in Harmatta's specification. The defendant makes the precise Harmatta product by the specific Harmatta process.

CASES ON CONSTRUCTION OF CLAIMS.

It is a well established principle of law that the claims of a patent should be construed in accordance with the specification to cover the actual invention made by the patentee.

This fundamental principle of law is stated by the Supreme Court in *Rubber Company* v. *Goodyear*, 9 Wall. 788, 795:—

> "A patent should be construed in a liberal spirit, to sustain the just claims of the inventor. This principle is not to be carried so far as to exclude what is in it, or to interpolate anything which it does not contain. But liberality, rather than strictness, should prevail where the fate of the patent is involved, and the question to be decided is whether the inventor shall hold or lose the fruits of his genius and his labors."

In *Wicke* v. *Ostrum*, 103 U. S. 461, the Supreme Court said (p. 568):—

> "To make the claims of his letters-patent intelligible, they must be read in connection with the specifications to which they relate."

Where, as in this case, the product of the process is new it is well settled that the product claims should be held valid as covering the new product made by the process described in the patent. See

Cochrane v. *Badische Anilin & Soda Fabrik*, 111 U. S. 293, 296-310.

Smith v. *Goodyear Dental Vulcanite Co.*, 93 U. S. 486, 493.

Downes v. *Teter-Heany Development Co.*, 150 Fed. Rep. 122, C.C.A. 6th Cir.

Inasmuch as the defendant has practiced the exact process set forth in the Harmatta patent and has produced the articles made by that process, it has infringed all the claims of the patent when those claims are construed, no matter how narrowly, to cover that process and its product.

CHAPTER II.

THE HARMATTA FILE-WRAPPER

(Vol. II, pp. 1353–1466).

The history of the application for the Harmatta patent in the United States Patent Office is nothing but the usual story of the struggle of an applicant to obtain a patent for his real invention. Harmatta was especially handicapped in being a foreigner living in Hungary and he was further unfortunate in the selection of solicitors who were Canadians. In spite of these handicaps Harmatta through his solicitors persistently endeavored from the beginning to frame claims, based on the clear disclosure in his application as originally filed of the spot welding invention ultimately patented in the patent, which claims would meet the approval of the Patent Office.

Harmatta's original specification describes not only the process of spot welding, which necessarily results in the spot welded articles (pp. 1360, 1361), but also a process of *line* welding with beveled edge rollers. The roller process was almost immediately eliminated from the application by the amendment of May 10, 1904.

We are not concerned with this line roller welding but with that part of Harmatta's original specification which describes his spot welding process by which he obtained the spot welded articles.

His original specification stated (p. 1356):—

> "My invention relates to a process of and apparatus for manufacturing metal articles of all kinds, in particular those of the thinnest sheet metal by direct electric welding."

In this statement Harmatta definitely placed his invention in the art of electric welding created by Professor Thomson in which the welding heat is created directly in

the work itself at the joint between the articles to be welded by the resistance at and near that joint to the passage of the electric current which was of small voltage and large volume. He definitely excluded those processes which are not electric welding and which employ indirect methods of heating, such as electric arc (Benardos U. S. patent) or hot blocks (Benardos German patent) or by conduction (Thomson riveting patent No. 396,015).

As we have above pointed out, the conditions, inherent in direct electric welding, require the use in the welding circuit of conductors and electrodes of very low resistance, commonly made of copper and of large cross-section. They are so shown in the drawings (p. 1466) accompanying Harmatta's original specification.

The figures of the original application were six in number; of these figures 1 and 5 are figures 1 and 2 of the issued patent and the two parts of original figure 6 are figures 4 and 5 of the patent.

Figures 2 and 3 of the original specification show rollers for continuous *line* welding. These rollers are narrowed and pointed at the edges, so that, while having nothing to do with spot welding, they embodied Harmatta's new principle of operation of concentrating the current by the shape of the electrodes themselves. This is a distinct departure from the disclosure of the Thomson lap welding patent No. 444,928, in which the rollers are wide and overlap the work so that the work itself, and not the electrodes, concentrates the current and determines the extent of the weld. All reference to rollers in the specification was cancelled May 10, 1904 (p. 1366). At this time the figures of the drawings which relate to line roller welding were also eliminated. From this date the application described solely pointed electrode spot welding.

Concerning Fig. 1 (Fig. 1 of the patent) showing the pointed electrodes localizing or concentrating the current

and pressure for spot welding the original specification states (p. 1357):—

> "Fig. 1 is a view illustrating the welding of two metal sheets of equal thickness, intermittently or at certain *spots* only."

Of Fig. 5, now Fig. 2 of the patent, the original specification says:—

> "Fig. 5 is a side elevation of a welding device (also illustrated in part in Fig. 1) according to which the pressure is exercised by pin shaped electrodes, the form of which may be suited to the particular purpose in view, and which may be adapted to work on the smallest possible surface of contact."

The electrode spot weld is described as follows (p. 1358):—

> "As Fig. 1 shows, the two sheet metal or other bodies, the edges of which lie upon each other, are introduced between the two electrodes *a*, *b*. Of the latter the one, somewhat prior to welding or only during the welding operation, is pressed upon the other, as the arrow shows; or both electrodes may be caused to exert pressure on the objects to be welded."

The electrode spot welding is further described in the original specification (p. 1360):—

> "Thus if it is required to weld, for instance, sheets of metal only at particular places, the apparatus shown in Fig. 5 may be advantageously employed, the electrodes *a*, *b* having the form of pins. The lower electrode *b* is then inserted in the conductor *d* whilst the upper electrode *a* is carried by an arm *s* and can be turned by means of a hand-lever *t* carried by said arm *s* on the shaft *u* in such manner that *the*

> *points* of the electrodes *a*, *b* approach and recede from each other. If then two superposed sheet metal ends to be welded together are introduced between the electrodes, and the latter then firmly pressed together and the circuit closed, *a small round, very sharply defined place of welding is caused which perfectly answers the purposes of a rivet.* In this event, also, especially in the case of thin vessels, which are not required to withstand great pressure, the pressure on the place of welding may at the right moment be exactly regulated or kept within the proper limits."

This is a full and accurate description of the process of electrode spot welding which necessarily results in the spot welded articles.

This description is entirely adequate as a basis for both the method and article claims of the issued patent.

Of the claims of the original specification, the first two covered the process of electrode spot welding and were broad enough also to cover Harmatta's roller line welding which later he elected not to cover. Claims 3 and 4 were limited to roller line welding only (pp. 1361, 1362).

It seems to us unnecessary to follow in this brief the various amendments of the specification and claims by which the claims were limited from time to time. From these amendments it appears clearly that, instead of expanding his application, Harmatta was constantly making it more specific, and that he was at all times seeking a suitable claim to protect his invention.

For example, the claim accompanying the amendment of May 14, 1904, calls for—

> "The process of electrically welding thin sheets and the like, consisting in applying pressure *at the place of welding* of the two superposed metallic objects to be united, etc." (Vol. II, p. 1373.)

This claim was cancelled and another claim substituted in an amendment of November 26, 1904. This claim calls for an electric welding process—

> "Consisting in first pressing intimately together the two superposed metallic objects *at the very point* at which the welding joint is to be formed, and then whilst maintaining the intimate pressure, heating the objects by passing an electric current through them exactly *at said point* in which the welding is to be effected" (p. 1375).

This claim is unquestionably directed to Harmatta's process of spot welding.

Of the three claims filed in the amendment of November 17, 1905, the first calls for—

> "Passing an electric current through them [the sheets] *exactly at said point*, in which the welding is to be effected" (p. 1385).

The second claim calls for—

> "a pressure limited to a material *point*" and
> "a current also limited to said material *point*" (p. 1385).

In the substituted claim filed with the amendment of May 18, 1906, the process is described as—

> "applying suitable electrodes on the metallic objects *at the very point* at which the welding joint is to be formed", and applying the pressure and current (p. 1395).

The substitute specification filed December 3, 1906, contains a good description of the process of electrode spot welding. This specification says (p. 1399):—

> "My process consists in applying suitable electrodes

on the metallic sheets *at the very point* at which the welding joint is to be formed, then causing said electrodes to exert a pressure on the metallic sheets sufficiently to press the metallic sheets intimately together *at the point* at which the welding joint is to be formed, then heating the metallic sheets by passing an electric current through said electrodes and through the metallic sheets, and finally maintaining the pressure of said electrodes on the metallic sheets during the passage of the electric current through the electrodes and metallic sheets."

(p. 1402:) "*At the place where the electrodes a, b exert pressure* therefore (Figs. 2 and 3), that is to say, where the current is able to flow through the bodies to be welded without having to pass through a layer of air and form sparks, *the metal is heated to welding heat.* Immediately this temperature is reached, the continous pressure effects the desired union, that is to say, welding of the two thin metallic sheets 5 and 6, without injury by perforation or burning, in the manner explained, having taken place, even if the sheets are extremely thin."

The claim accompanying this specification (p. 1403) is in substance a repetition of the first paragraph of the description just quoted. It is plainly an attempt to define the process of electrode spot welding, the spot being referred to as a "point". This claim was rejected December 15, 1906 (p. 1404), and was cancelled and two new claims filed December 5, 1907 (p. 1405). The second of these claims clearly defines electrode spot welding, as follows (p. 1405):

"2. The process of electrically welding *thin* metallic sheets, consisting in *applying suitable electrodes on the metallic sheets at the very point of which the welding joint is to be formed*, then causing said electrodes to

exert a maximum pressure on the metallic sheets sufficiently to press the metallic sheets intimately together *at the point* at which the welding joint is to be formed, then heating the metallic sheets by passing an electric current through said electrodes and through the metallic sheets, and maintaining the maximum pressure of said electrodes on the metallic sheets during the passage of the electric current through the electrodes and metallic sheets."

This claim, while not as good a definition of electrode spot welding as are the claims of the issued Harmatta patent, is objectionable only because of its possible breadth.

The claim was finally rejected in the Patent Office action of February 9, 1909 (p. 1411), in which the Patent Office said:—

> *"It is thought that if there is any patentable matter in this case it resides in the securing of the sheet metal parts together by means of the small round, sharply defined place of welding which answers the purpose of a rivet, as is set forth on page 6 of the original specification."*

This states the invention exactly.

Harmatta adopted this suggestion of the Patent Office in his amendment of January 28, 1910, in which he filed an amended specification (pp. 1414-1417) with two claims aimed more specifically at the electrode spot welding process. In the remarks accompanying this specification he said (p. 1412):—

> *"Great care has been taken not to describe anything which was not illustrated or explained in the original disclosure."*

In the next Patent Office action of March 22, 1910 (p. 1418), claim 2 was said to be allowable, and claims 1,

5, 6, and 16-20 of the Rietzel patent No. 928,701, issued July 20, 1909, were suggested to Harmatta under the provisions of Patent Office Rule 96 for the purpose of exciting an interference. Thereupon in an amendment March 31, 1910, Harmatta added these Rietzel claims to his application.

The interference was declared April 26, 1910 (p. 1425), and to it claims 2-4 of Rietzel were added June 12, 1911 (p. 1430). This interference was decided in favor of Harmatta, October 17, 1912 (p. 1431). On October 23, 1912, Harmatta filed the specification and claims now appearing in his patent and the application was allowed October 31, 1912 (p. 1454).

There is nothing in the history of this Harmatta application but the common history of an applicant who has amended his application both as to the specification and claims in such a way as to define accurately the nature and scope of his invention.

Harmatta's original application included both electrode spot welding and line roller welding. Claims on the latter were rejected by the Patent Office and were dropped from his application by his amendment of May 10, 1904 (p. 1366), although we believe that he was entitled to claims properly limited to that process which was new with him.

Electrode spot welding he saw was new and he persisted from the beginning in seeking a claim adequate to protect that invention. He never desisted in his efforts to obtain suitable claims and when the Patent Office pointed out to him that his claims were too broad and that they should be limited to the making of a spot weld that would take the place of a rivet he proceeded to cut down the scope of his claims and to limit them more closely to his specific process and its product.

Harmatta had the right to use the knowledge that he

obtained from the art, including the Rietzel patent, to enable him to define properly and accurately his invention. There is nothing in the patent that is not fully described in the original specification. *The drawings are the same as those of the original specification. The claims both for his process and his product read upon the original description and drawings. Harmatta, therefore, was clearly entitled to these claims.*

The law is well established. It is stated in *General Electric Company* v. *Cooper Hewitt Electric Company*, 249 Fed. Rep. 61, C. C. A. 6th Cir., p. 64:—

> "The rule is that insertions by way of amendment in the description or drawing, or both, do not hurt the patent, if the insertions are only in amplification and explanation of what was already reasonably indicated to be within the invention for which protection was sought—'something that might be fairly deduced from the original application.' *Hobbs* v. *Beach*, 180 U. S. 383, 395, 21 Sup. Ct. 409, 45 L. Ed. 586; *Cleveland Co.* v. *Detroit Co.* (C. C. A. 6) 131 Fed. 753, 857, 68 C. C. A. 233; *Proudfit Co.* v. *Kalamazoo Co.* (C. C. A. 6) 230 Fed. 120, 123, 144 C. C. A. 418; *Cosper* v. *Gold*, 36 App. D. C. 302."

See also:

Hobbs v. *Beach*, 180 U. S. 383.

Western El. Co. v. *Sperry Co.*, 58 Fed. 186, C. C. A. 7th.

Gen. El. Co. v. *Morgan Gardner Co.*, 168 Fed. 52, C. C. A. 7th.

Process claims may be added to an application which had originally only claims for a machine.

John R. Williams Co. v. *Miller Co.*, 107 Fed. 290, 292.

Conversely, we submit, product claims may be properly added to an application which describes and claims a process which produces such product.

Harmatta's file wrapper discloses nothing but the usual struggle of an inventor to obtain a patent for his invention. Throughout he complied with all the requirements of the law and of the rules of the Patent Office.

CHAPTER III.

THE McBERTY PRIOR USE DEFENSE.

When a patent attains the commercial importance of the Harmatta patent, someone will almost always be found, as experience has shown, who, having perhaps dabbled in the general subject-matter in connection with which the invention was ultimately developed, pretends, and even makes himself think, that he made the invention long before the patentee. This was recognized and pointed out by the Supreme Court in the *Barbed Wire Patent* case, 143 U. S. 275, 284, where the court said that

> "almost every important patent, from the cotton gin of Whitney to the one under consideration, has been attacked by the testimony of witnesses who imagine that they had made similar discoveries long before the patentee had claimed to have invented his device."*

This is human nature. "The wish is father to the thought." Such claims are sometimes entirely fraudulent, but are often set up by men who are more or less unconscious that there is no real basis for their contention. There being a strong motive to create such a defence, and human memory being frail, it is easy for a man, particularly if he was so situated that he *might* have made the invention, to persuade himself that he is really entitled to the credit of some one else's great achievement; and corroborating witnesses can always be found who, under the stimulus of skilful suggestion, will subscribe to an essentially untrue structure of testimony.

The present case is no exception in this particular, for here we find as one of the chief defenses an alleged prior

*See also the *Telephone* and *Incandescent Lamp* cases referred to, page 188 *infra*.

use, claimed to have been carried on by one Fred B. McBerty in February, 1901, at Warren, Ohio.

It appears that McBerty, while in the employ of the Warren Electric & Specialty Company of Warren, Ohio, in February, 1901, was in charge of a butt welder machine which was in use for butt welding the ends of the guard rings of electric desk fans. These rings were the circular wires forming parts of the wire guard frame which enclosed the fan blades. The fan blades were secured by rivets to the arms of a center or "spider", the hub of which was fastened to the shaft of the electric motor. The defendant alleges that McBerty made some experiments with this butt welding machine in the course of which experiments he arrived at the idea of spot welding. It is even asserted (but as a belated emendation of the story), that by this spot welding process McBerty welded a "trayful" (about a dozen or fifteen) of fan blades and spiders which were assembled in completed fans and went into the regular commercial product of the Warren Company known as "Peerless" fans.

This McBerty prior use contention was not passed upon in the majority opinion of the Court of Appeals for the Sixth Circuit holding the Harmatta patent invalid for lack of invention. Judge Denison, in dissenting from the conclusion of the Court that the bill should be dismissed, must have found the defence to have failed.

The first and perhaps the most obvious answer to the McBerty story is that even if it were all true, it amounts only to an *abandoned experiment*, ineffective to defeat the Harmatta patent; for it is admitted that after the one alleged trayful of fan blades and spiders had been produced, the process was wholly abandoned by McBerty and the Warren Company, and that thereafter the company's fan blades were always *riveted to the spiders* as they had been before, the machine being continued in use only

for butt welding the guard rings, and no further spot welding experiments, or anything of the sort, ever having been performed on it. It is not asserted by McBerty that any of this alleged spot welding was done except between February 15, 1901, and the end of that month. McBerty never did any other spot welding on this or any other machine until many years later, long after the date of Harmatta's application. Nothing would ever have been heard about the 1901 McBerty experiments had it not been for the Harmatta patent and the necessity of building up a defense against it.

But the story *is not true;* in fact it is *demonstrably false.*

In the first place, the whole setting of the story and the history of its development are such as to make it improbable to the last degree. There are certain outstanding facts about it, requiring no detailed study of the record, and easy of comprehension, which in our opinion are of such controlling importance that this Court, on the basis of these facts alone, will reject the McBerty defense and find that the District Court was in error in sustaining it.

Briefly summarized, some of these salient outstanding facts are as follows:—

(1) The story first saw the light (in a very different form from its present form) in 1913, when McBerty, who was then an officer of a concern known as the National Electric Welder Company, which had been notified by the plaintiff, the Thomson Company, that it was infringing the Harmatta patent, worked up the defense in conjunction with his counsel, J. Nota McGill, and approached the Thomson Company with an offer to sell his "prior use" evidence to the Thomson Company, to be by that company suppressed, in consideration that his company should receive a license under the Harmatta patent on better terms than others were to receive,— a proposition which

was rejected by the Thomson Company with the contempt it deserved.

(2) The next appearance of the story was when McBerty, later on in the same year, 1913, communicated it to counsel for the defendant in the Barney & Berry case in the First Circuit. These counsel made a thorough investigation of it, collecting many affidavits with the aid of McBerty, who spent two weeks of his time helping them; and when the story was fully before them, these counsel decided that it would hurt and not help their case, for the reasons, first, that they did not believe it, and second, that even if it were true, all it amounted to was an abandoned experiment.

(3) After the decision of the Court of Appeals for the First Circuit sustaining the Harmatta patent in the Barney & Berry litigation, McBerty's company, the National Electric Welder Company, took a license under the Harmatta patent, in which license the validity of the patent was recognized,— conduct wholly inconsistent with McBerty's claims to prior invention.

(4) The story as now told by McBerty is a radical departure from the story told by him in 1913, to his own counsel and to counsel for the Barney & Berry Company, in many particulars. Two of the most significant are:

(a) The matter of the "trayful" of fan blades and spiders alleged to have been united by spot welding and to have gone into the commercial fans sold by the Warren Company was unthought of in 1913. In 1913 McBerty made no pretense that he had spot welded more than one spider to its blades and said definitely that no commercial use was made of the process. He did not even allege that this one fan blade structure was ever embodied in a finished fan. Now he says (evidently for the purpose of curing, if possible, the obvious defect of his previous story in that it showed nothing but an abandoned experiment), that all

the fan blades and spiders of about a dozen fans were spot welded by him, that the same were assembled into finished fans and that these went into the commercial output of the Warren Company.

(b) Although McBerty in 1913 told his own counsel that he was "unable to identify the exact date" when he "did this experimenting", he now comes forward with a *dated* alleged original sample of his work (Exhibit M) upon which is stamped the date "2/15/01", this having been deliberately fabricated, as we believe, for the purpose of supplying an element of proof previously lacking, namely, contemporaneous record evidence.

McBerty certainly never thought enough of his 1901 experiments to apply for a patent on the process he now claims that he then invented, although he has taken out many patents (Vol. I, p. 441).

His present company, the Federal Machine & Welder Company, is a manufacturer of machines to be used in infringement of the Harmatta patent (Vol. II, pp. 849, 850), so that he is strongly interested to defeat the patent.

These broad facts, all standing out on the face of the record, and requiring no detailed examination of the evidence, are enough, to say the least, to cause the Court to look with grave suspicion upon the story; and, coupled with the fact that it is admitted that the process was never carried any further than the welding of this one alleged "trayful of fans", a work which could not have occupied more than an hour or so, these facts are in our belief controlling, and require that the whole matter be dismissed as improbable and as at best an unsuccessful abandoned experiment.

But this is by no means all. When we come to analyze the story in detail, we shall find, as is usually the case in a situation of this kind, that when subjected to careful

analysis it breaks down *in details*. We shall, later, fully discuss these details and the inherent contradictions in the story as told.

But outside of these contradictions and the entire failure to make out a consistent story *there are at least three reasons why it is not possible that McBerty's story can be true*, namely:—

(a) That the butt welding machine on which McBerty alleges that he did this work did not have room to insert the fan blades and spiders which he says he spot welded on it;

(b) That the machine did not have a transformer capable of supplying enough current to it to do spot welding; and

(c) That McBerty did not have in 1901 the sheet steel spiders which he says that he then spot welded.

Moreover *the only concrete items of evidence* which defendant produces to support McBerty's present story utterly fail to do so: —

(d) The 1901 catalogue of the Warren Company, which is alleged to show a cut of a fan with spot welded blades, is proved by defendant's own witnesses to have been gotten out months before the machine was built on which McBerty asserts that he did his spot welding so that the cut could not have been made from a fan with such blades; and

(e) "Defendant's Exhibit M", the piece of a spot welded spider and fan blade stamped with the date "2/15/01" and with McBerty's name, is clearly spurious and fraudulent.

The demonstration of these points — each of them fatal to McBerty's contention — will require a great deal of patience on the part of the Court, as it involves a necessarily tedious analysis of the testimony.

We shall first direct the Court's attention to the broad outstanding facts in the situation which we have above suggested; we shall then ask the Court's patient consideration of the evidence which in our view positively proves that the McBerty story cannot be true; and we shall particularly discuss the misleading catalogue cut and the alleged specimens upon which McBerty relies, and consider the evidence of the "corroborating witnesses".

McBERTY'S EFFORT TO SELL HIS EVIDENCE TO THE THOMSON COMPANY.

In December, 1912, when the Harmatta patent issued, McBerty was a half owner and the active manager of the National Electric Welder Company (Vol. II, p. 848), which company he had formed in 1911 to manufacture electric welding machines for both butt welding and spot welding. (The Harmatta process had been introduced in the United States in 1904 at the works of the National Enameling & Stamping Company, of Baltimore, Maryland, and prior to 1911 this company had built and put into use many spot welding machines (*supra*, p. 14), so that by this time spot welding was common knowledge and McBerty was entirely familiar with it.)

Upon the issuance of the Harmatta patent, notice of infringement was immediately served on McBerty's company, the National Electric Welder Company (Vol. II, p. 745).

Then McBerty, who had unquestionably set up in the plant of the Warren Company in 1901 a butt welding machine and very likely had done some unsuccessful experimenting of some sort on it, bethought himself of these abandoned experiments, and saw a chance, by distorting and enlarging upon them, of working up a case of alleged "prior use" which might enable him to make terms with the Thomson Electric Welding Company, plaintiff's prede-

cessor, owner of the Harmatta patent. He consulted his attorney, J. Nota McGill, got up some affidavits and *attempted to sell this evidence to the Thomson Company, to be by that company suppressed.*

McBerty's animus in the matter is shown by the very first letter which he wrote to his counsel, J. Nota McGill, December 9, 1912. McBerty said in that letter (Vol. II, p. 950):—

> "I have been looking up my witnesses and etc., on this matter, and *if we have any chance at all* I am confident that we can either put up an extraordinary good fight *or be in a position to ask the Thomson Company for a satisfactory settlement.*"

A "settlement" was what he was looking for.

Mr. McGill, replying to this suggestion as to a settlement with the Thomson Company on the basis of this evidence, said in his letter to McBerty under date of December 13, 1912 (Vol. II, p. 949):—

> "In thinking over the Harmatta patent, it occurs to me that it might be to your interests not to enter into any alliance with other manufacturers having for its object the making of terms with the Thomson Company. If your evidence is as it now appears to be sufficient to invalidate the Harmatta patent,* the Thomson people would doubtless be willing to negotiate with you on satisfactory terms, provided they were not compelled to similarly deal with your competitors. If there is any reason for giving the latter the benefit of the defense you have, then of course they will continue to be competitors. I suggest these things for your consideration."

Mr. McGill, in a letter to McBerty's company dated

*This remark was made before Mr. McGill had made any investigation whatever of McBerty's claims.

January 4, 1913 (Vol. II, p. 943), after stating that he has written a letter to the Thomson people about the matter, goes on to say that "*the affidavits submitted are not wholly sufficient*, but I do not want to suggest any change until after I see the machine", and adds:—

> "*If the Thomson people will grant you a license you can afford to surrender your evidence.*"

Thereupon McBerty armed with affidavits from Brown and Lipps, whose later affidavits are in evidence (Vol. I, pp. 478, 450), called on Mr. Fish, of counsel for the Thomson Company, in the hope of arranging for some settlement on the lines suggested. Mr. Fish, after hearing McBerty's story, told him, as McBerty himself admits, that on his own statement the whole matter was only "*an abandoned experiment*" which was not sufficient to defeat the patent (Vol. II, p. 753).

McBerty's proposition was, as he himself testifies, that the Thomson Company should

> "*buy me out*" (p. 753).

This proposition was of course declined by the Thomson Company.

Thus McBerty's effort to sell himself and his evidence to the Thomson Company failed. **He was willing "to surrender" his "evidence" upon condition that he himself should receive a consideration either in the form of a license under the patent on more favorable terms than other manufacturers, or in the form of an outright purchase price.**

McBerty's proposition was little short of blackmail and the suggestion that in the event of a trade the evidence should be surrendered,— that is that the defense should be suppressed,— would have been a gross fraud on the public, who were entitled to the defense, if it in fact existed.

McBerty's course in this matter reflects anything but credit upon his own honesty and credibility.

The reasons for McBerty's bitter enmity against the Thomson Company and for his determination to break the Harmatta patent by any means possible are thus made obvious.

Such an attempt to sell the proofs of an alleged prior use casts discredit on the veracity and good faith of the person who claims to have made that use, and gives good ground for rejecting the story.

In *Chadeloid Chemical Co.* v. *Thurston Co.*, 220 Fed. Rep. 685, before Judge Sanborn, in the District Court of the Northern District of Illinois, there was urged an alleged prior use based mainly on the testimony of men who had attempted to sell the evidence of priority to the patent owner with an offer to destroy the proofs. The court said:—

> "The facts recited are so flagrant (to say the least) that no court would be justified in paying the slightest attention to this prior use evidence, since the testimony of Hulin and Matthes is vital." (Page 693.)

COUNSEL FOR THE BARNEY & BERRY COMPANY THOROUGHLY INVESTIGATED THE McBERTY STORY, CONCLUDED THAT IT AMOUNTED TO NOTHING AND DECIDED NOT TO RELY ON IT IN THE BARNEY & BERRY CASE.

Balked in his efforts to sell himself and his evidence to the plaintiff, McBerty in 1913 put the whole story in the hands of Messrs. Edwards, Sager & Wooster, counsel for the Barney & Berry Company, which was then being sued in the First Circuit by the plaintiff on the Harmatta patent, and spent *two weeks of his time* assisting Mr. Howe of that firm to collect the evidence, taking him around to see all the witnesses and aiding in the drawing of numerous

affidavits (Howe, Vol. I, p. 300, Q. 7). In the course of this investigation Mr. Howe, with McBerty's help, collected affidavits from the following witnesses in addition to McBerty himself, namely:— Lipps, Browne, Gilder, Meeney, Estabrook, Bean, Wolcott, Bettiker, McCurdy, Lewis, Bechtel, Pendleton, Pilz, Wakefield, Ulp and Pfile, — all of which affidavits are in evidence and printed in Vol. I of the record, pp. 450–483.

This mass of testimony was carefully investigated not only by Mr. Howe, but also by Mr. C. V. Edwards, head of the firm of Edwards, Sager & Wooster and one of the most experienced and successful patent lawyers at the New York bar, Mr. Edwards himself also having a talk with McBerty personally; and these attorneys decided both that McBerty's story was not entitled to belief, and that if it were true it showed only an abandoned experiment which would not anticipate the patent (Vol. I, p. 292, Q. 12). Mr. Edwards testifies that it was decided not to rely on this "prior use" as a defense in the Barney & Berry case,

> "First, because after reading the affidavits and after hearing Mr. McBerty's version, **neither I nor Mr. Sager nor Mr. Warren* believed the story.**
>
> "Second, because it seems to me that even if all that Mr. McBerty said had happened, had actually happened, **it was nothing more than an accidental experiment,** and whatever its nature was, it was evidently considered by him to be useless for any practical purpose." (Vol. 1, p. 292.)

Naturally Mr. Edwards decided not to prejudice his

*Mr. Warren was the General Manager of the Toledo Electric Welding Company which was the manufacturer of the infringing spot welder used by the Barney & Berry Company, the defendant in the Massachusetts Case, the defense of which the Toledo Company assumed.

chances in the Barney & Berry case by relying upon any such defense. All this is brought out in Mr. Edwards' deposition in the present case (Vol. I, p. 288) taken by us in answer to the scandalous charges made on behalf of defendant to the effect that the evidence of the alleged McBerty prior use was wrongfully suppressed by Mr. Edwards and that the case was collusively tried.

FOLLOWING THE DECISION IN THE BARNEY & BERRY CASE, McBERTY'S COMPANY TOOK A LICENSE UNDER THE HARMATTA PATENT AND ADMITTED ITS VALIDITY.

After the final decision of the Court of Appeals for the First Circuit holding valid the Harmatta patent, the National Electric Welder Company, of which McBerty was active manager, took a license from the Thomson Company under the Harmatta and other patents.

These facts are brought out in the opinion of Judge Westenhaver in *Thomson Spot Welder Company* v. *National Electric Welder Company*, 260 Fed. Rep. 223, a suit on the license contract, who states as follows:—

> "Complainant's patent, No. 1,046,066, issued to Johann Harmatta, has been adjudicated to be valid by the United States Circuit Court of Appeals of the First Circuit. This adjudication became final in July, 1916. *Thereafter complainant entered into a license agreement with the defendant, the National Electric Welder Company, granting it permission to use the Harmatta and other patents owned by complainant* until the expiration of the Harmatta patent. This agreement, in addition to other terms, contains a clause whereby the National Electric Welder Company *admits the validity of the Harmatta patent*, and of all patents relating to spot or point welding machines now owned by complainant, and agreed not to ques-

tion or contest, during the life of said Harmatta patent, the validity or terms thereof, or the application thereof to the process of spot or point welding machines utilized therefor. Substantially all other makers of machines for the utilization of this process, it is alleged, have entered into similar license agreements." . . .

"*The conduct, in particular, of Fred P. McBerty, active manager of the National Electric Welder Company, shows a course of conduct directly inconsistent with a past purpose or with a sincere intention to observe in good faith that part of the agreement binding the National Electric Welder Company not to question or contest the validity of the Harmatta patent.* His co-operation with other defendants over a long period, in procuring evidence, making experiments, and planning for an attack on the Harmatta patent, is not justified by the excuses put forward in his behalf, namely, that evidence of prior use in his possession may be forced from him by legal process."

The conduct of McBerty in taking a license for his company, the National Electric Welder Company, under the Harmatta patent, in which license the validity of the patent was recognized, is, we submit, *wholly inconsistent* with the claim he now makes that he himself originated the invention covered by this patent.

McBERTY'S PRESENT STORY DEPARTS FROM AND ENLARGES UPON HIS 1913 STORY NOTABLY IN TWO ESSENTIAL PARTICULARS.

As we have shown, in the year 1913 McBerty told his story at length to his own attorney, J. Nota McGill, and worked up affidavits for the purpose of "selling out" his evidence to the plaintiff, for suppression; and thereafter again, in the same year, he told it to Mr. Howe, of Edwards,

Sager & Wooster, attorneys for the Barney & Berry Company; and at that time personally assisted Mr. Howe in collecting affidavits and evidence in support of his story, besides himself giving a long and full affidavit to Mr. Howe.

It is very fortunate that we have now the full detail of the story as it was told by McBerty in 1913; for a comparison between the 1913 version and the present version, shows most radical discrepancies. The two stories are very different. In particular that told in the present record varies from that told in 1913 by the incorporation in it of at least two most significant and surprising additions, designed to overcome two fatal deficiencies in the 1913 version — the lack of any pretense of commercial use — and the lack of contemporaneous record evidence. There is no hint in the 1913 story of the alleged facts on which these additions are based. They appear for the first time in the testimony in this case.

McBERTY'S STORY OF 1913.

The subject was opened by McBerty in a letter to his attorney, Mr. McGill, dated December 9, 1912 (Vol. II, p. 950). In this letter he acknowledges receipt of a copy of the Harmatta patent, and adds:—

> "In connection with this subject I am interested in knowing whether, *if* I manufactured a machine and did spot welding on it before the application was made in England or the United States in a satisfactory and practical manner, would this have bearing on the granting of the patent at the present date to the Thomson Company.
>
> "I have been looking up my witnesses and etc. on this matter, and if we have any chance at all I am confident that we can either put up an extraordinary good fight or be in a position to ask the Thomson Company for a satisfactory settlement."

Mr. McGill replied under date of December 10, 1912, to the effect that such machine would constitute an anticipation of Harmatta,—

> "*provided it was not an abandoned experiment.* In other words *if the machine was constructed and used in an experimental way and then abandoned it will not be available as a defense.* If, on the other hand, it was long in use and was used where it could be seen by people connected with the establishment, it would constitute a good defense." (Vol. II, p. 951.)

Thereupon, under date of January 2, 1912 (an obvious mistake for January 2, 1913), McBerty wrote another letter to McGill (Vol. II, p. 944) describing his efforts to get statements from witnesses, referring to the fact that the welding machine on which he did the spot welding was originally designed for a butt welder, pointing out that the transformer used with this machine was shown by the books to have been turned over on January 25, 1901, to the fan department of the Warren Company, and then making this significant statement:—

> "I have also samples of spot welding which was done on the welder at the time *we did this experimenting*, and while *we are unable to identify the exact date* we can approximate it within two or three months."

We call attention in passing that *this is a plain statement that he did not have at that time a dated specimen of his work such as he now pretends to produce as his Exhibit M.* If he had had Exhibit M when he wrote this letter he could not possibly have written it, because one of the very samples he was talking about would have borne upon its face the evidence to "identify the exact date". He does not now assert that Exhibit M was only found by him after the

letter was written, but says that he had found it in his tool box in 1911 or 1912 (Vol. II, p. 840, X-Q. 784).

McBerty's next letter to McGill, February 10, 1913, explains that the Warren Company after "this experimenting", abandoned the idea of uniting the fan blades and centre spiders by welding because the dies which they then had to stamp out the blades also punched the rivet holes required for the rivets by which they united the blades to the spiders, and if spot welding were to be employed no such rivet holes should be punched on account of their unsightly appearance. It would therefore have been necessary to go to the expense of getting new dies which would stamp out blades without punching rivet holes (Vol. II, p. 947).

McBerty's next step was to try to induce the Thomson Company to buy out his evidence for the purpose of suppressing it, as above pointed out, and when this attempt failed he was in a good mood to put up the "extraordinary good fight" mentioned in his letter to McGill of December 9, 1912 (Vol. II, p. 950).

His opportunity came in the Barney & Berry suit when counsel for the Toledo Electric Welder Company, which was defending that suit, sought to make the defense of the McBerty prior use. Mr. McGill first turned over all the data in his possession to Mr. Edwards, of counsel for the Toledo people, in September, 1913 (McBerty, Vol. II, p. 762, Q. 280); and later McBerty assisted Mr. Howe in a full and careful investigation which was completed in October, 1913 (Vol. I, p. 300).

The detailed McBerty affidavit prepared at that time (Vol. I, p. 437), 1913, should be carefully read in order that the Court may have well in mind *the maximum extent of the assertions made by McBerty in 1913.* This affidavit occupies eleven printed pages and was sworn to on October 9, 1913. It must not be forgotten that even this affidavit was made twelve years after the alleged date of the ex-

periments which it purports to describe. There is no reason why even then McBerty and his other witnesses should have more than the vaguest recollection of what had happened so many years before; but certainly their recollection in 1913 is as good as their recollection when they testified in this case six years later.

McBerty, in the 1913 affidavit, says that he desired to produce a cheaper fan for the season of 1901, and that he decided to make parts of this cheaper fan of iron instead of brass, and to unite the ends of the guard rings by butt welding, and describes the building and use of his butt welding machine. As to spot welding, he says (p. 440):—

> "I demonstrated to my own satisfaction and also that of others that the machine would butt weld satisfactorily, . . . and also that sheets or plates of metal could be welded together in spots less in area than the overlapping portions of the plates."

He then explains how this was done, and proceeds to describe (p. 441) the spot welding which he says he did. This is what he says (p. 442):—

> "In demonstrating the practicability of this idea **I took one of the steel fan blades and centers** and welded the blades to the center arm, each blade being secured to the arm by a number of welds in different spots. This was done by me in the spring of 1901, this being the time the machine was finished and its capability of butt welding the ends of the fan guard rings demonstrated."

This is *absolutely all* that McBerty, in this carefully prepared affidavit of 1913, claimed to have done by way of spot welding. He asserts only that in *one case* he welded the four fan blades to the centre or spider, and *he does not even assert that in this one case was this welded structure*

put into a complete fan, with motor, guard, etc. Indeed, in the portion of *the affidavit immediately following that* above quoted, he seems to say that this one welded structure was cut up by him and one blade of it (produced and marked Exhibit O attached to his affidavit) kept as a specimen of the work, the rest apparently being thrown away. **There is not the least hint that he used the spot welding process to unite fan blades and spiders of a dozen or fifteen fans, and that these went into the regular commercial output of the Warren Company and were sold, or even that he spot welded one spider to its blades, which went into a fan that was sold.**

The rest of the affidavit consists mainly of an explanation of the manner of operating the welding machine and of an explanation of the reasons why spot welding was not used in the commercial manufacture of the fans.

Those reasons were that the fan blades and spiders already in stock had been punched for rivets, and it would make a botched job to have open rivet holes in blades united to the spiders by spot welding,* that as the punching had been done there would be no saving in spot welding over riveting, that further expenditure would be necessary to make the tools and jigs necessary to perform the spot welding, that as it was in the month of February, which was well along in the fan season, it would be impracticable to make a change for that season, that the riveted fans

*A significant circumstance in this connection is that while McBerty in this affidavit of 1913, asserted that a principal reason why the spot welding of blades to spiders was not adopted was because the fan blades were already punched with rivet holes (see also McBerty's letter to McGill, February 10, 1913, Vol. II, p. 947; Lipps' affidavit, Vol. I, p. 454; Brown's affidavit, Vol. I, p. 484), such punching is flatly denied by McBerty in his testimony in this case (Vol. II, p. 740) because he wishes to contend that he spot welded blades to spiders that were put on fans that were sold. Fans with blades having unfilled rivet holes would have been unsalable.

had proved satisfactory, and that they did not want a second set of apparatus or a duplicate set of unpunched stock, as would be necessary for the spot welded fans (Vol. I, p. 443).

None of these reasons would have prevented the spot welding of fan blades for the succeeding season of 1902 or subsequent seasons. The admitted fact that no attempt was made to do such spot welding in 1902 or later is a strong indication that *the real reason* for its non-user was that McBerty had never in fact practiced that process in 1901, or that if he had tried experiments pointing in that direction he had accomplished nothing and abandoned the idea as a failure.

The principal other persons whose affidavits were obtained in 1913 by Mr. Howe were E. C. Lipps (Vol. I, p. 450) and Frank G. Brown (p. 478), each of whom executed an affidavit on October 6, 1913.

The affidavit of Lipps may be summarized: That in the year 1901 he was employed until *April 29* at Cleveland when he returned to Warren and entered the employ of the Trumbull Mfg. Company (this date being fixed by his time book), that while in the employ of the Trumbull Company he frequently visited McBerty and that on one of his visits he found McBerty "putting in a transformer of larger capacity" in the welding machine, that spot welding as well as butt welding was performed on the machine and he produces "Exhibit H" attached to his affidavit "as a kind of a sample" of the welding done, that he saw steel fan blades welded to the hub arms in a number of distinct spots, that McBerty told him that "he proposed the use of the spot welding of the fan blades to the centers in producing a commercial cheap grade of fans," that the fan blades were "drilled" with rivet holes, that the spot welding of the fan blades to the centers as proposed by Mr. McBerty "was not adopted commercially," that

"at that time the space between the clamp arms" of the machine "was not sufficiently deep to permit the sheets to be welded together to extend sufficiently low down when placed between the electrodes" so that "we bent the ends of these electrodes upwardly so as to allow the sheets of metal to enter between the sheets of the electrodes at a sufficient extent to place the weld at a spot desired", that "in the original machine" the two pieces of the base plate "were separated by a piece of fibre to insulate them which extended the whole length of the base plate", and that later the "fibre piece was cut out directly under the spot where the weld was made".

Many of these statements absolutely contradict McBerty in the essential features of his testimony in the present case as we shall show.

Brown's affidavit, Vol. I, p. 478, is to the effect that he was in the employ of the Packard Motor Car Company of Warren in 1901, that one Sunday "previous to May 6, 1901," he visited McBerty who told him that he had done spot welding on his machine, that he saw no spot welding done, that he produces a fan blade spot welded to an arm cut from a fan center or spider marked "Exhibit B" as a specimen "precisely the same" as those shown him by McBerty. He confirms McBerty's statement that the fan blades at that time were "punched for rivets in accordance with the practice of the Company, which had always employed rivets for this purpose," and that the securing of the fan blades by spot welding was not adopted by the Warren Company.

There is no hint in the affidavits of Lipps and Brown (or in the affidavits of others), all of which were prepared under McBerty's supervision, of anything but a futile and abandoned experiment, which, if Lipp's Exhibit H is a true specimen, never amounted to spot welding in any sense, as we shall show (*infra*, p. 177).

The other affidavits (pp. 463–477) add nothing whatever of consequence to McBerty's own story.

None of the 1913 *affidavits, including that of McBerty himself, suggest or hint that any spiders having welded blades went into complete fans that were sold, or indeed that any one such complete spot welded spider and blade structure ever was made as a commercial product.*

Mr. Howe, who obtained the affidavits as the basis of making a defense of prior use in the Barney & Berry case, was, of course, very eager to get evidence that spot welding had been practically used by McBerty and that what he had done was not a mere abandoned experiment, but he was definitely told by McBerty that there had been no commercial use of the process. Mr. Howe testifies (Vol. I, p. 302, Q. 11):—

> "He (McBerty) said that they had made one fan, one complete structure — by a complete structure I mean the central part which has been referred to as spider, with a blade secured to each of the arms of the spider. In this connection I was very insistent to learn if more of these fan blade structures had not been made, and especially I was desirous of establishing that there had been some commercial use made of these fan structures, because I believe this would have made our case of prior use immeasurably stronger; but *I was unable to find out by McBerty or any one that there had been a commercial use of them, in fact* **was told there was no commercial use;** the reason was that Mr. Gillmer [the president of the Warren Company] had decided not to put them into commercial use because of financial considerations, and that ended the matter."

In fact, as Mr. Howe testifies, McBerty did not even assert that "a complete fan structure, that is, including the

motor, fan, guard, etc., and including spot welded blades, had been built" at that or any other time (Howe, Q. 12, p. 303).

McBerty likewise told Mr. Edwards that no spot welded fan blade "had been sold or put into use and that none had been welded except upon the one occasion referred to" (Edwards, Vol. I, p. 292, Q. 11).

In answer to this clear and definite testimony of both Mr. Howe and Mr. Edwards, McBerty has only two mutually contradictory statements to offer.

He said in his first deposition that *he did not recollect whether or not he told Mr. Howe about the fans going into commercial use.* We quote his testimony (Vol. II, p. 865):

> "*X-Q.* 1140. Did you tell Mr. Howe of any assembled fans with these spot welded spiders and blades?
>
> *A.* I don't definitely recollect that, either.
>
> *X-Q.* 1141. Did Mr. Howe ask you about that?
>
> *A.* That I couldn't say.
>
> *X-Q.* 1142. Don't you recall that it interested Mr. Howe to know whether these spot welded spiders and fans had gone into commercial use?
>
> *A.* It would, yes, sir.
>
> *X-Q.* 1143. *But you don't recollect telling him?*
>
> *A. No.*
>
> *X-Q.* 1144. *That was a point you either held back or didn't know about?*
>
> *A. I didn't know about definitely.*"

Later on, apparently realizing the fatal character of this admission that he in 1913 did not know definitely whether any spot welded fans went into commercial use, and that he did not recall telling Mr. Howe about the matter, he recants from this position in a second deposition and testifies (Vol. II, p. 960, Q. 6) that he *did* tell Mr. Howe

about these spot welded complete fans which went out to the trade in 1913.

It is perfectly clear that the testimony of such a witness is not to be accepted against the word of these two highly reputable lawyers, Mr. Edwards and Mr. Howe; and indeed it goes without saying that anything and everything which McBerty had told Mr. Howe about any commercial use, would certainly have been incorporated in the affidavit by Mr. Howe, who was intensely interested in showing commercial use if possible.

Mr. Howe also recognized the extreme importance of getting *contemporaneous record evidence* of the date when the work was done. He says (Vol. I, p. 302):—

> "I was somewhat concerned in the case because almost everything seemed to depend upon recollection of the persons who knew anything about the matter, and I was therefore especially urgent to get some documentary evidence or contemporaneously dated articles of some kind which would corroborate the recollection of the witnesses. Such material seemed very scarce, and *I again and again urged it upon Mr. McBerty that it would be of very great assistance if some such contemporaneous material could be obtained.* We scanned the situation again and again, and apparently Mr. McBerty did everything that was possible for him to do to produce all the tangible date evidence that he could."

No such date evidence was produced.

On the McBerty story as told in 1913, first to his attorney, McGill, and later as set forth to its fullest extent both in McBerty's own affidavit and in the affidavits of others prepared with his assistance, absolutely no argument can be made of an effective prior use. The situation lacked two absolutely vital essentials

of a successful prior use defense, namely: *first*, the element of commercial use as distinguished from abandoned experiment, and, *second*, contemporaneous record date evidence.

It was after all this evidence had been collected and considered that McBerty took a license for his company, the National Electric Welder Company, in which the validity of the Harmatta patent was admitted (*supra*, p. 133).

Then, in 1917, the so-called "Welding Patents Investigating Committee", an association of manufacturers and users of unlicensed spot welding machines, was organized to fight the Harmatta patent, and this aggregation got in touch with McBerty, and through him has presented in this case a reconstruction of his old discredited story, the futility of which McBerty had himself practically admitted by taking a license under the Harmatta patent.

McBERTY'S PRESENT STORY.

McBerty's story had been rejected by Mr. Edwards first, as incredible and as obviously an abandoned experiment. The fact that it showed no commercial use of spot welded fans was a most important circumstance in fixing its experimental character. There was no contemporaneous evidence as to the date of the experiments. Mr. Howe had "again and again urged it upon" him that it would be of very great assistance if some commercial use could be established and some "contemporaneously dated articles" could be found (*supra*, p. 144).

These points were not lost upon so resourceful a man as Mr. McBerty; and so when he took the stand in this case six years later he was prepared to meet *both* difficulties.

First. McBerty now asserts that a trayful (some twelve or fifteen) of spot welded blades and spiders were put together by him and went into completed fans as part of the regular commercial output of the factory. This *new*

addition to the story is put in for the obvious purpose of attempting to overcome the fatal objection to the whole defense that at best it amounted to nothing but an abandoned experiment.

Second. McBerty now produces his "Exhibit M", a fan blade spot welded to a portion of a spider and bearing stamped on its face the date "2-15-01" and the name "F. McBerty". This is produced in order to supply the necessity for contemporaneous record date evidence, hitherto lacking. This Exhibit M, McBerty says, he dug up from his tool box in 1911 or 1912 (X-Q. 784, Vol. II, p. 840). But in his letter to his own attorney, McGill, of January 2, 1913 (the letter is dated by mistake January 2, 1912, but the context shows that it was really January 2, 1913), McBerty said:—

> "I have also samples of spot welding which was done on the welder at the time we did this experimenting, and while **we are unable to identify the exact date** we can approximate it within two or three months." (Vol. II, p. 945.)

This is utterly inconsistent with the existence at that time of the dated Exhibit M which McBerty says he had found a year or two before. This sort of thing was exactly what Mr. Howe was looking for; and McBerty's only explanation of why Howe did not see it is that he (McBerty) deliberately suppressed it (X-Q. 823, Vol. II, p. 842), — an explanation which is, we submit, obviously not entitled to belief.

If all that McBerty now says were true, the defense of prior use would still fail, because his alleged operations, even so, did not amount to more than an abandoned experiment. His alleged work on the fan blades and spiders was done in less than a week (X-Q. 445, Vol. II, p. 821) and could have been done in an hour or so if done

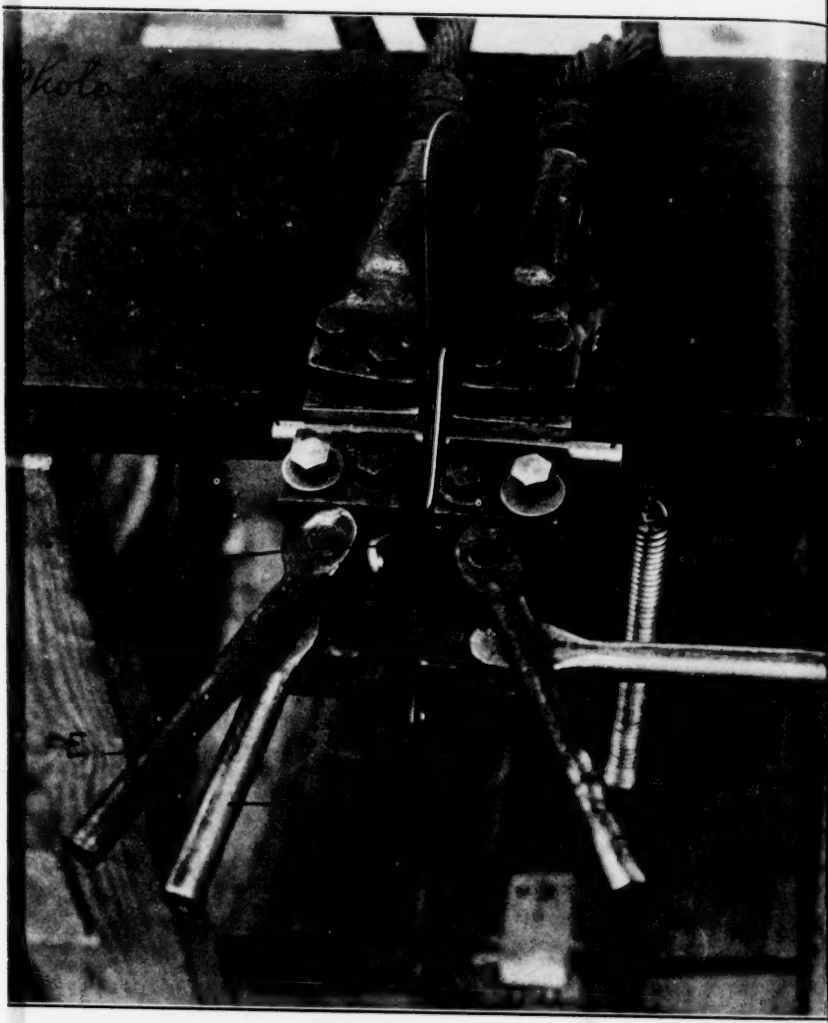
at ordinary speed (X-Q. 459). The fact, if it be a fact, that in the course of that experiment a trayful of fan blades and spiders were spot welded and were put into fans as part of the commercial output of the factory is very far from being a practical commercial use of the process. This we,shall discuss more fully in a subsequent section (p. 206).

But McBerty's story, emphatically, is *not* true

THE EVIDENCE PROVES POSITIVELY THAT McBERTY'S STORY CANNOT BE TRUE.

We have now set forth certain broad and, as we believe, controlling facts about the McBerty defense which are easily stated and require no particular study of the record. We have shown that the story was first developed in 1913 — about twelve years after the alleged work was done — as a means for inducing the Thomson Company to give McBerty's company a license under the Harmatta patent on more favorable terms than others were to receive; that McBerty first attempted to sell his "evidence" to the Thomson Company for suppression, for the consideration that his company should be given such a license under the Harmatta patent, or for an outright purchase price, which proposition was rejected by the Thomson Company; that thereupon McBerty told the story to counsel for the Barney & Berry Company, and that these counsel made a very thorough investigation of it with McBerty's assistance, and concluded that it was not true, and that if true it amounted only to an abandoned experiment; that following the decision sustaining the Harmatta patent in the Barney & Berry case, McBerty for his company took a license under the Harmatta patent, admitting its validity; and, finally, that the story he now tells differs from and enlarges upon the 1913 story as told to his own counsel and to counsel for the Barney & Berry Company in the

two vital points, namely, the "trayful of fans" and the dated Exhibit M, without which additions no argument could possibly be made for an effective prior use. We believe that these broad facts, coupled with the admitted abandonment of the process after the making of the single alleged trayful of fans, point unerringly to the conclusion that the McBerty operations, whatever they were, amounted only to an unsuccessful abandoned experiment, insufficient to anticipate the Harmatta patent in suit.



At the outset of this discussion we stated that a story of this kind, unless it is true, usually breaks down when its details are carefully analyzed and patiently tested, and that in the present case it is definitely proved by certain demonstrated facts that McBerty's story is not and cannot be true. We now proceed to state these facts,— a process which will inevitably require a detailed consideration of the evidence. Later we shall show other fatal inconsistencies in the details of the testimony which we believe refutes itself. The two propositions of a broader character which we now advance are these:—

(1) That the butt welding machine on which McBerty claims to have done his spot welding in 1901 was incapable of doing the work he claims to have done on it, for two reasons: (a) because there was no room in the machine for the insertion of a fan spider with or without four blades attached to it, such as McBerty says he spot welded on the machine; and (b) because the transformer with which that machine was equipped in 1901 was incapable of delivering a current sufficient to do spot welding, although adequate for the butt welding for which it was designed.

(2) That in 1901 there were no such sheet steel spiders available to McBerty as he says he welded to the fan blades.

We now proceed to consider these propositions in order.

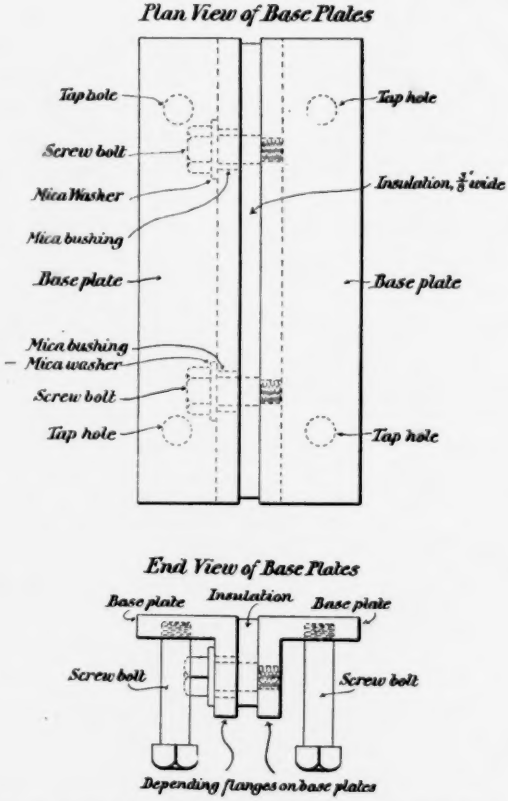
DEFENDANT'S EXHIBIT B.

THE SPACE LIMITATIONS ON McBERTY'S 1901 MACHINE WERE SUCH AS TO MAKE IT IMPOSSIBLE TO SPOT WELD FAN BLADES TO FAN CENTRES ON THAT MACHINE.

There is in evidence as Defendant's Exhibit B a machine alleged to embody certain physical parts of McBerty's 1901 butt welder, on which he claims to have done his spot welding, but this exhibit is admittedly only a recent reconstruction and differs from the 1901 machine in at least two vital respects — in its assemblage and manner of mounting on the bench and in the transformer used with it.

We show on the opposite page a photograph of this machine *as it is now set up*. It is composed of two movable platens marked respectively A and B, each mounted pivotally upon an angle iron (lettered respectively C and D) and each supplied with current from the opposite poles of a transformer, not shown in the photograph. G, G are copper electrodes held tightly by sliding clamp jaws operated by the cam handles E, E and fastened in position by nuts. In the photograph the fan spider or centre is shown at H, and a fan blade to be welded to the spider at I. F, F are cam levers or handles pivoted respectively on the two angle bars which bear respectively against the platens A and B. When these handles are moved, they operate to force the platens A and B toward each other and therefore to press the electrodes G, G carried by these platens A and B into close contact with the work to be welded. When the current is turned on, a welding heat is generated in the work between the electrodes and when these electrodes are forced together by means of the handles F, F the weld is completed.

The only parts of this device Exhibit B claimed to have been present in the 1901 machine are the two angle irons constituting base plates on which the movable platens are



pivoted, perhaps the swinging platens themselves and one pair of handles. The insulation between the plates is new (McBerty, Vol. II, p. 817, X-Q. 379). The spot welding electrodes are new (Vol. II, p. 501, Q. 98, 99; p. 818, X-Q. 384–388). The jaws of the clamps are new (Vol. II, p. 817, X-Q. 380, 381). At least one pair of handles is new (Vol. II, p. 817, X-Q. 378). The arrangement of the device on the bench (a vital matter to the operation of welding four blades to a spider as we shall now show) is new. The transformer which supplies the welding current is not the same as it was originally (*infra*, p. 163).

In 1911 what was left of the old machine was found by McBerty in the scrap pile in the garret of the Peerless Company (successor to the Warren Company) where it had been for years. It was then bought by McBerty and by him reconstructed and remounted in its present form in 1917 (McBerty, Vol. II, p. 832, X-Q. 645; p. 838, X-Q. 748–750; p. 834, X-Q. 688; p. 855, X-Q. 951).

It will be seen that, as this machine is now set up, the greater part of it projects forwardly in front of the bench and that there is an open space between the base plates, providing ample room for the insertion of a fan spider and fan blades between the electrodes. But, as is completely established by the evidence to which we shall shortly refer, when the machine was first set up in 1901, the space between the base plates, for their full length from rear end to front end, was filled in by an insulation plate of fibre, and the machine was mounted with its front edge flush with the front edge of the bench so that no parts projected forwardly of the bench except the handles. We insert two sketches showing the details of the base plates and bolts with this insulation plate in place.

It will be obvious that when the device was set up in this manner there was no room for inserting a fan spider

between the electrodes, much less for inserting a fan spider with attached fan blades. The fact that the original 1901 mounting of this machine was as we have described it is stated by many witnesses, and it is substantially admitted by McBerty himself, who, although he says that his "notion" is that the parts projected forwardly from the bench then substantially as they do now, will not state so

Base Plates of Exhibit B as Originally Set Up.

positively (Vol. II, p. 835, X-Q. 706–710) (if he did he would be contradicted by more than half a dozen witnesses including several called by defendant). McBerty definitely admits that as the machine was originally set up in 1901, there was this insulation plate between the two parts of the device, and that because of the presence of this insulation plate there was no room for inserting a fan spider. He says (Vol. II, p. 819, X-Q. 405):—

> "There was an insulation in the center of the machine which prevented us getting our work down at the proper height."
>
> "*X-Q.* 409. And you used that [a bent electrode] because there was an insulation piece running the whole length between the bottom plates?
>
> *A.* Running the whole length, and I could not get my blade in low enough to reach it."

It is therefore definitely admitted even by McBerty himself that when the device was originally installed in 1901 its space limitations were such that it could not do the work of spot welding fan spiders to fan blades, which McBerty claims to have done on it, because there was no room into which to get the spider and four blades, and that in this respect at least Exhibit B in evidence departs from the original construction.

McBerty further says that because of this space limitation he substituted for the straight electrodes, such as are present in Exhibit B, *Z-shaped electrodes* so as to raise the points of contact between the electrodes high enough above the strip of insulation to accommodate the pieces to be welded. He says in his affidavit of 1913 (Vol. I, p. 446):—

> "I distinctly remember that at that time [*i. e.*, the early part of 1901] the space between the clamp arms 3 and 4 was not sufficiently deep to permit the sheets to be welded together to extend sufficiently low down

> when placed between the electrodes 31 and 32, when these electrodes were straight, and so we bent the ends of these electrodes upwardly so as to allow the sheets of metal to enter between the electrodes to a sufficient extent to place the weld at the spot desired."

These bent electrodes he describes as Z-shaped and he says that it was with these Z-shaped electrodes that he made his first effort "to weld fan blades to the center" (Vol. II, p. 819, X-Qs. 402–408). He admits, however, that the Z-shaped electrodes would not do the work because "we could not supply sufficient power with these Z-shaped electrodes" (X-Q. 403). Obviously they would too flexible. He says that the only kind of electrodes which he used successfully for spot welding were the straight electrodes such as are present in Exhibit B (X-Q. 391) and that in welding his fan blades he used these straight electrodes (X-Q. 403).

It is obvious, then, that until a further change had been made in the manner of mounting the machine after his admittedly unsuccessful experiments with the Z-shaped electrodes, it was impossible for McBerty to have done the work that he now claims to have done on this machine.

McBerty says that he did away with this space limitation and got the necessary room *by cutting away the forward part of the insulating piece* between the base plates. This would of course not have given him room for inserting the spider with its four arms unless he had also moved the whole device forward on the bench so that it projected beyond the edge of the bench as it does in Exhibit B.

A flat and vital issue of fact is thus raised: *Did McBerty cut away this insulating piece and change the mounting of the device so as to make it project forwardly from the bench, and if so, when did he do it?* In this connection it should

be borne in mind that his allegation is that he did this spot welding work on the fan blades and spiders in *February, 1901.* He makes no assertion that he ever did any of it after that month (X-Qs. 613, 617, 620, Vol. II, pp. 830, 831; see also Smith, X-Qs. 337, 338, Vol. I, p. 520) and his dated Exhibit M purports to have been produced on February 15, 1901.

It is vital, then, to McBerty's story that it be proved that he had cut away this insulation piece and mounted the machine so that it projected forward from the bench *at least as early as February, 1901.* So he testifies (p. 820):—

"*X-Q.* 418. Now, what time of the year did you cut away that fibre?

A. That fibre was cut away when we first welded our blades.

X-Q. 419. What time of the year was that?

A. That was in the early spring.

X-Q. 420. What do you mean by early spring?

A. In either January or February." . . .

"*X-Q.* 423. And you made these fan blades early in January?

A. Either early in January or the first of February, that is, the first part of February."

"*X-Q.* 425. How do you identify February as the month?

A. I identify February as the month on account of my first piece of work being produced, which was produced in February.

X-Q. 426. What is that, Exhibit M?

A. I don't remember the number of the exhibit.

X-Q. 427. That has stamped on it February 15, 1901, I believe?

A. Yes, sir."

But on this vital point McBerty is not only refuted by a large number of wholly unprejudiced witnesses called by the plaintiff, but also by the testimony of defendant's own witness Lipps.

Taking first the testimony of Lipps, we find that Lipps was in Cleveland and not in Warren at all, as shown by the time book produced by him, Exhibit G, until *April 29, 1901*, and that until after that date he never could have seen this McBerty machine, so that anything he testifies to about the machine must have related to dates subsequent to April 29, 1901. (See Lipps' affidavit, Vol. I, p. 451; and Lipps' testimony, Vol. II, p. 919, X-Q. 54.) Lipps testifies that when he first saw the machine(which was as we have seen *after* April 29, 1901) the insulating fibre between the two base plates *ran the whole length between them.*

We quote his testimony (Vol. II, p. 923):—

> "*X-Q.* 80. Do you recall in the original machine the fibre between the two base plates ran the whole length?
>
> *A.* Yes sir, that is why we could not get a sheet in between."

And he testified about the use of the bent or Z-shaped electrodes. He says:—

> "I distinctly remember that at that time the space between the clamp arms 3 and 4 was not sufficiently deep to permit the sheets to be welded together to extend sufficiently low down when placed between the electrodes 31 and 32 when these electrodes were straight, and so we bent the ends of these electrodes upwardly so as to allow the sheets of metal to enter between the electrodes to a sufficient extent to place

the weld at the spot desired."* (Vol. II, p. 922, X-Q. 74.)

And he further distinctly testifies, thereby rebutting McBerty's contention on the point, that the machine *did not protrude beyond the front edge of the bench.* We quote (p. 923):—

"*X-Q.* 76. Did it (the machine) stick out as far as it does now?

A. It had been altered repeatedly. When first made it set down.

X-Q. 77. Covered the whole bench?

A. Yes, sir.

X-Q. 78. Didn't stick out at all?

A. It didn't stick out at all at first."

He testified that it was *at some later time* that the machine was moved out to project beyond the bench (X-Q. 79).

This testimony of Lipps is, by itself alone, we submit,

*Note that this testimony of Lipps speaks of the welding of "*sheets of metal*", not of fan blades. Lipps admitted on the stand that he never saw any fan blades welded on the machine (Vol. II, p. 917, Q. 17) although he had asserted the contrary in his affidavit (Vol. I, p. 453). Exhibit H produced by Lipps in connection with his affidavit as a sample of the work that was done on the machine, is composed not of a fan blade and centre, but of *two portions of armature lamination discs* (Vol. II, p. 453). This Exhibit H, which was kept by Lipps as "a sample" of McBerty's work, Vol I, p. 453, is a mere "*stick*" and not a spot weld at all (Gravell, Vol. I, p. 323; Wagner, Vol. I, p. 345). It is exactly the kind of thing which might be expected to result from an attempt to weld with a current of only one volt, which was the maximum welding current that the 1901 transformer was capable of supplying (*infra*, p. 163). A "stick" is the result of a mere fusing of the oxides on the surfaces of the metal pieces, and is to be sharply distinguished from a real spot weld, in which the body of the metal itself fuses and merges (Vol. I, p. 369). Defendant makes no assertion that Exhibit H is a specimen of successful spot welding, and did not offer it in evidence. It is exactly the sort of unsuccessful experimentation which McBerty may have done in 1901 on this machine if he did anything.

sufficient to overthrow the whole McBerty story, for it definitely proves that (whereas it is vital to McBerty's story, as we have shown, to prove that the insulation fibre had been cut away and the machine mounted so as to project beyond the bench as early as February, 1901) this defendant's witness, who could not possibly have seen the machine until after April 29, 1901, distinctly remembers that when he first saw it the insulation fibre had not been cut away, that the machine did not project beyond the bench and that in the experiments which he saw, it was necessary to use the impractical expedient of the Z-shaped electrodes in order to get any pieces of metal into the machine.

But this is not all. McBerty *never* cut away the insulation fibre or mounted the machine so that it projected forward of the bench (both of which steps were necessary to make room for his doing the work on the fans which he says he did) at least until long after 1901, if the testimony of at least five unbiased witnesses familiar with the machine is to be believed.

L. C. Brewer, called by plaintiff, is the chief witness on this point. His deposition is to be found at Vol. I, pp. 269–284. He was the first and only regular operator on this machine, and he worked on it for about four years, doing butt welding on the fan guards for the Warren Company (p. 270, Qs. 13–18). He therefore, if anyone, ought to know whether or not this machine was mounted as McBerty says, with the forward end projecting beyond the bench as in Exhibit B, and whether there was any slot in the insulation or in the bench to provide room for welding fan centres to fan blades. He definitely testifies that the machine was mounted on a solid fibre plate, that there was no slot in it while he worked on the machine, and that *no part of the machine except the handles projected beyond the bench*. We quote his testimony (Vol. I. p. 272):

"*Q.* 24. You have referred to a piece of fibre under the clamps. How big was the fibre in its area?

A. About 8 x 10, as I remember it.

Q. 25. Were there any slits in this piece of fibre?

A. Not while I worked on this machine."

"*Q.* 27. Did the clamps extend beyond the edge of the bench?

A. Yes, the length of the handles. Did you mean the clamps that clamp the ring?

Q. 28. Yes.

A. They did not. Not to my knowledge.

Q. 29. To make this matter exactly clear, what parts of the device did extend beyond the edge of the bench?

A. The handles of the machine.

Q. 30. Do you recall the work of putting this electric welding device on your bench?

A. Yes, sir.

Q. 31. State whether or not the bench was cut with a slit for this machine.

A. It was not."

Brewer made a sketch of the machine as it was when he worked upon it which is in evidence as Plaintiff's Exhibit 32 (Vol. I, p. 462), which shows no part of the machine projecting beyond the bench except the handles and no slot in the bench between the two halves of the machine.

Brewer knows of no spot welding being done on this machine, and knows of no other method of fastening the blades on the fan spiders by the Warren Company than riveting (p. 274, Qs. 51, 52).

C. R. Brewer, called by plaintiff, was employed by the Warren Company in the fan department during the years 1901, 1902 and 1903 and saw the machine every day (Vol. I, p. 285, Qs. 14–16). He likewise testifies that the

machine as then used was mounted upon an insulated fibre plate (Q. 17, Vol. I, p. 285), that the bench and fibre plate were not slotted (Q. 18), and that the machine did not protrude beyond the bench (Q. 20, p. 286). *He never knew fan blades to be attached otherwise than by riveting and never knew of any spot welding being done on this machine* (Q. 24, p. 286; Qs. 30, 31, p. 287).

C. G. Wolfe, called by plaintiff, aided McBerty in building this machine (Qs. 8, 9, Vol. I, pp. 309, 310), and worked at the Warren Company's factory until 1902 (Qs. 5, 6). He testifies to the same effect, namely, that the machine was set on fibre "flush or nearly flush with the bench" (Qs. 13, 14, p. 310). *He knows of no spot welding having been done on the machine* (Q. 18, p. 311).

L. L. Little, called by plaintiff, was one of the men who made the mechanical parts of the machine (Q. 10, Vol. I, p. 311). He testifies to the same effect, to wit, that there was no slot cut in the bench (Q. 15), and that "there was no space to put anything there at all, unless itwas a very narrow piece" (Q. 16). All fan blades were riveted to the spiders (Q. 23, p. 312), *and Little never heard of any other welding being done on it except butt welding* (Qs. 17, 18, p. 312).

G. I. Spade, called by plaintiff, at the period in question was in charge of the motor assembling department for the Warren Company (Qs. 12, 13, Vol. I, p. 314) and frequently saw the machine in operation (Qs. 15, 16, p. 282). He testifies to the same effect as the other witnesses, to wit, that the machine as he knew it was mounted upon a fibre plate (Q. 18), and that it was not possible to insert blades or steel pieces between the welding electrodes "unless it would have been a very narrow piece, say about one-half inch" deep (Qs. 20, 21, p. 315). He testifies that the photograph of the present machine shows the machine projecting too far from the bench to represent

correctly the original mounting (Q. 18). *He never heard of any spot welding being done on the machine* (Qs. 24, 25, p. 315).

These witnesses do not remember that the base plates were angle irons (L. C. Brewer, Q. 41, C. R. Brewer, Q. 21, Wolfe, Q. 13, Little, Q. 14, and Spade, Q. 12). This is strong corroboration of their testimony that the device was set into a fibre base plate and did not protrude beyond the edge of the bench, because in that case the depending flanges of the angle irons would be imbedded in the fibre base and be concealed by it and by the fibre strip between them. These witnesses had no reason to take the machine apart as would be necessary in order for them to see the depending flanges of the angle irons.

Moreover, *defendant's* witnesses corroborate the clear and explicit testimony of these five men, to the effect that the machine is set up differently now from what it was originally, in that originally it did not project over the front of the bench as it does now. Thus Lipps says that it has been "altered repeatedly" and "*didn't stick out at all first*" (X-Qs. 76, 78, Vol. II, p. 923).

Defendant's witness Smith makes a similar admission at X-Q. 218, Vol. I, p. 510, saying that "the clamping device did not extend so far out past the edge of the bench at the Warren Electric & Specialty Company as it now does, as it is mounted".

Defendant's witness Craft admits that the machine as originally set up had fibre between the base plate and the bench (X-Q. 98, Vol. II, p. 781) and is unable to say that the machine projected over the bench (X-Q. 213, p. 789).

There was no reason why the device *should* project beyond the edge of the bench for butt welding the fan guard rings, for no part of the rings extended below the clamps in this operation. To have so arranged it would have made it weak because it would have been held in

place only by the rear bolts. It would also have been in the way of the workmen passing back and forth in front of the bench.

McBerty admits that when he found the device in the garret of the Peerless Company (successor to the Warren Company) in 1911 it was mounted on a slate base which "ran all the way under the plates" so that there was no room for the insertion of a fan blade (Vol. II, pp. 832, 833, X-Qs. 660–670).

Numerous other changes would have had to be made in this machine by McBerty besides cutting away the insulation fibre and moving the machine forward, in order to adapt it to do the work of spot welding fan blades to spiders. For example, the horizontal distance between the two base plates would have had to be increased from the 3/8 inch which it was originally (McBerty, Vol. II, p. 828, X-Qs. 566–568) to the 3/4 inch or so which intervenes between the two plates as the machine stands now (McBerty, X-Q. 569, p. 828), in order to make room laterally between the base plates to accommodate the fan blades and spiders. This would have necessarily involved:

(1) Cutting a new groove in the support or table into which the depending flange of one of the base plates was to be set;

(2) Putting in a new and wider piece of insulation fibre between the base plates at their rear;

(3) Relocating the vertical screw bolts attaching one of the base plates to the bench;

(4) Readjusting the horizontal bolt which holds together the rear ends of the base plates; and

(5) Removing altogether the forward horizontal screw bolt holding the two plates together, because with this bolt in place there would be no room for a fan spider with attached blades.

All this involves, as will be seen, a very considerable amount of work and readjustment, and it is incredible that if these changes had been made, such a man as L. C. Brewer, the first and only regular operator on the machine for four years, would not have known about them.

It is, therefore, clear:

(1) That the 1901 butt welding machine as originally built and set up could not possibly have been used for spot welding fan blades to spiders, because of the space limitations on the machine; and this is admitted even by McBerty. Exhibit B is *not* the machine as it originally was installed in 1901, but it is a mere 1917 reconstruction, with many new parts, and mounted in a vitally different manner. The pretence that its present mounting and arrangement is a counterpart of the 1901 mounting and arrangement depends purely upon oral testimony, and the inconclusive oral testimony of McBerty alone at that, which oral testimony is refuted by many witnesses.

(2) That the changes necessary to be made on this machine to make it possible for it to accommodate fan spiders and fan blades to be spot welded, were certainly not made until after April 29, 1901, is clear from the testimony of defendant's witness Lipps, whose date is established by the record evidence of his time book; whereas the contention of McBerty and his witnesses, on which this whole defence is predicated, is that complete fan blades and spiders were successfully welded on the machine in February, 1901. No witness claims that any practical use was made of the process after the "trayful of fans" alleged to have been made in February, 1901, were completed.

(3) That unless the unsupported word of McBerty alone is to be believed as against the testimony of half a dozen unprejudiced witnesses, he *never* made the changes in the machine necessary to adapt it to accommodate a fan spider with attached blades, *at least until years after*

1901; and, as we believe, not until after he got the machine from the garret of the Peerless Company in 1911 and reconstructed it in 1917 to use as an exhibit in support of his prior use contention.

We therefore contend with the utmost confidence that it is positively proved that McBerty's story of spot welding fan blades and spiders in 1901 on this machine *cannot be true, because of the space limitations that there then were in that machine.*

McBERTY COULD NOT HAVE DONE SPOT WELDING WHEN HE SAYS HE DID IT IN 1901 BECAUSE HIS TRANSFORMER WOULD NOT GIVE SUFFICIENT CURRENT.

We shall now show that it was impossible for McBerty to have done any real spot welding at all on his machine at the time in 1901 when he testified that he did it, for the reason that *the transformer which was used with it at that time would not provide sufficient current to accomplish spot welding* when connected up with a 250 volt primary circuit which was the only one available (Vol. II, p. 780, X-Q. 83).

This transformer, as shown by the transformer book of the Warren Company, was one which had been sent to Freehold, N. J., and had been returned to the Warren Company and delivered to its fan department on January 20, 1901 (McCurdy, Vol. I, p. 689; McBerty's letter, Vol. II, p. 945.)

This transformer record book produced by defendant's witness McCurdy contains what purports to be a complete record of the characteristics of the transformer in 1901. The record shows that there was *only one turn on the secondary* and the least number of available turns in the primary was 222 (Vol. I, p. 688). With a primary current of 250 volts pressure, which was alone used at the Warren Company plant (Vol. II, p. 780, X-Q. 83), there-

fore a maximum pressure in the secondary circuit of only 1.1 volts could be produced (Gravell, Vol. I, p. 355),* *which voltage is too small to do any successful spot welding, although it was sufficient to do the butt welding of the guard rings for which it was designed* (p. 357). This is a positive electrical fact testified to by Mr. Gravell. *It is in no way contradicted by defendant.*

It should be noted that the voltage used by defendant in its spot welding demonstration on Exhibit B at the Ford plant was 4½ volts (Vol. II, p. 827, X-Q. 557).

In fact, with the transformer as it was originally the current was hardly sufficient even for butt welding. Little (Vol. I, p. 312, Q. 20), and Wolfe (p. 310, Q. 17), state that at first many of the butt-welded rings came apart at the welded joint.

The transformer was, therefore, changed, but not until after April 29, 1901, months after McBerty testifies that he did his spot welding and after spot welding had been entirely abandoned according to the testimony of both McBerty (Vol. II, pp. 830, 831) and Smith (Vol. I, p. 520). Defendant's witness Lipps expressly says in his affidavit, taken in 1913 with McBerty's knowledge and co-operation, that he "*recalls distinctly*" seeing McBerty change the device "*by putting in a transformer of larger capacity so that sufficient current could be supplied*", which change was made at some time after April 29, 1901, a date fixed by Lipps by his time book as that on which he returned to Warren from Cleveland (Vol. I, pp. 451, 452). He also so testified on the witness stand (Vol. II, p. 922, X-Q. 65). Defendant's witness Craft emphatically denies

*The secondary voltage bears to the primary voltage the same ratio that the number of turns in the secondary bears to the number of turns in the primary. So that with a given primary voltage and a given number of turns in the secondary, the less turns in the primary the higher the voltage in the secondary.

that the transformer now in the machine is the one which had been to Freehold (Vol. II, p. 779, X-Q. 70).*

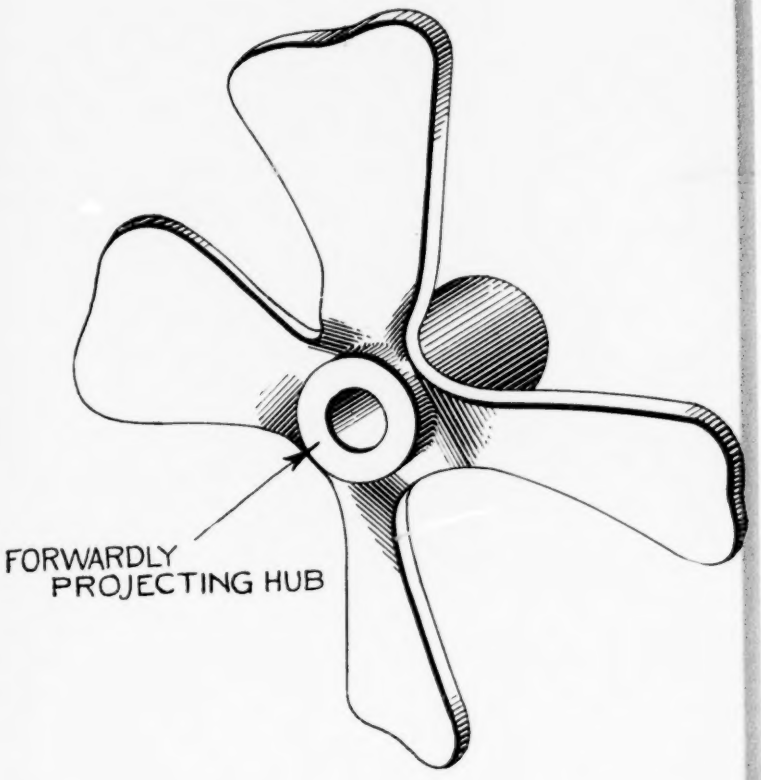
McBERTY COULD NOT HAVE WELDED THE G-TYPE FAN SPIDERS TO FAN BLADES BECAUSE THOSE SPIDERS WERE BRASS — NOT STEEL.

We come now to the third of the three propositions which we have advanced as a positive demonstration that McBerty's story cannot be true.

McBerty's story is that for the season of 1901 the Warren Company was about to manufacture a new and cheap type of fan, known as the G-type fan which had sheet steel spiders and steel fan blades and that he spot welded these parts together for a dozen or fifteen of these G-type fans. His Exhibit M has in it a piece of such a sheet steel spider. If, however, it is not true that the spiders for the G-type fans were of steel in 1901 — if they were of brass, then the story necessarily breaks down, because it is impossible to weld brass to steel and of course McBerty does not claim ever to have done so (Vol. II, p. 1016). Were, then, the spiders for the G-type fans in 1901 of sheet steel, or of brass?

McBerty admits that in 1900 the Warren Company had only brass spiders, and no steel spiders (Vol. II, p. 713, Q. 21, p. 1019), and there is no contention that McBerty or the Warren Company ever had any steel spiders prior to

*The transformer book gives the secondary voltages as 2, 2½, 3, 3½ and 4. This is inconsistent with the fact that there was only one turn in the secondary provided the primary current is 250 volts (Gravell, Vol. I, p. 355). The book has been in McBerty's possession for some time (McCurdy, Vol. I, p. 688). The voltage figures might have been filled in at any time. *The "1" in the column which gives the number of turns in the secondary stands unchallenged as establishing its original condition.* This "1" could not have been altered or erased without some tell-tale mark, but figures like the voltages could be *added* in a blank space.



The secondary voltages obtained are not a characteristic of the transformer but they depend on the voltage of the primary current.

1901. McBerty says, however, that in the new G-type fans produced during that year (on a "trayful" of blades and spiders of which he claims to have done this spot welding), the spiders were made of rolled steel, *i. e.*, sheet steel (Vol. II, p. 726, Q. 102).

In considering the evidence on this matter, the Court should first have in mind the difference in appearance and construction between the brass spiders which the Warren Company had always used before and the sheet steel spiders such as McBerty untruly claims were used in 1901 on the G-type fans.

In a *brass spider*, the hub and projecting arms (to which the blades are to be attached) are all integral parts of one casting. The shape of such a cast brass spider is illustrated in the sketch on the opposite page, and it will be seen exemplified in Plaintiff's Exhibit No. 51, a fan identified by Mr. Binder as the Warren Company's 1901 G-type fan (Vol. I, p. 386). It is identical with the illustrations of these G-type fans at page 17 of "Defendant's Exhibit No. 2, Warren Electric Specialty Company's 1901 Catalogue" offered (Vol. I, p. 499). Note particularly that a portion of this hub projects forward of the point from which the arms extend.

The *steel spiders*, on the other hand, such as McBerty claims to have used, are made up of two non-integral parts joined together, — first, the spider proper, which is stamped out of sheet metal, and second, a cylindrical steel hub upon which the spider proper is mounted. The construction of these parts is explained by McBerty at Vol. II, p. 723, and we illustrate it by a sketch opposite page 167, Figures 1 to 4. It will be seen that the steel hub is provided with "a small projection or collar" over which the spider is fitted, the back of the spider resting against the shoulder on the hub and the collar projecting slightly through the hole in the spider. The spider is

CAST BRASS SPIDER.

SHEET STEEL SPIDER AND HUB.

Fig. 1.

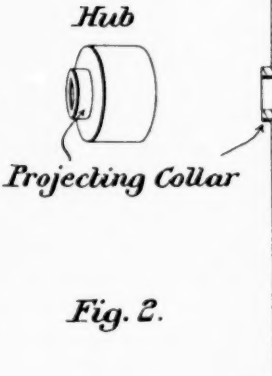


Fig. 2.

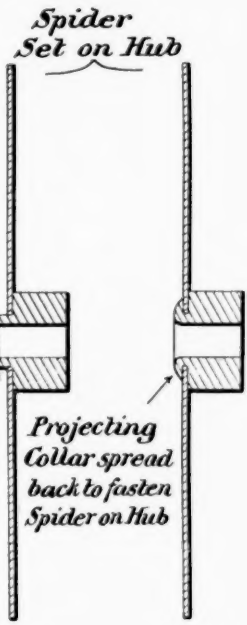

Fig. 3. Fig. 4.

then attached to the hub by upsetting this projecting collar, as shown in Fig. 4.

It is upon sheet metal spiders of this construction that McBerty says he spot welded his fan blades in 1901 (Vol. II, p. 1019). Such spiders are shown in the cut at page 589 of the Electrical World for March 4, *1909* (Plaintiff's Exhibit 64), showing the "Peerless Fans" (Gravell. Vol. I, p. 362) then made by the Peerless Company the successor of the Warren Company, and in the cuts of the Peerless Company fans in the *1910* Peerless catalogue (Plaintiff's Exhibit 68, see pages 4–7).

McBerty says that these sheet steel spiders were used in the G-type fans in 1901 (Vol. II, p. 726, Q. 102; p. 1019).

But if the Court will now look at the illustrations of these G-type fans at page 17 of the Warren Company's 1901 catalogue, it will see that these illustrations contradict him. Both show *a regular cast brass spider* like all the other fans shown in the catalogue.

Confronted by this fact (and he admits that at least the cut of the G-1 fan on this page 17 does show the cast brass spider, Vol. II, p. 972, RDQ. 2), McBerty attempts to avoid the difficulty by explaining that *this cut does not show the standard construction of this fan* (RDQ. 2, p. 972), an explanation that, to say the least, obviously requires strong corroboration.

Now it appears (Vol. II, p. 760) that the defendant has had in its possession (or at least that it has had access to) a considerable number of these G-type fans of 1901. But defendant *produced none of these fans in support of McBerty's assertion that the catalogue illustration did not show the standard construction of the fan*, and this fact alone is, we submit, enough to discredit his testimony on the point. If the cut was wrong, an actual specimen of the fan would easily correct the error, but no such correcting specimen is produced. *On the contrary the specimen of this type of*

1901 *G-1 fan which the plaintiff located and produced as Plaintiff's Exhibit 51* (Vol. I, p. 385) *has this regular cast brass spider just as is shown in the catalogue.*

McBerty's contention, therefore, that the G-type fans were made in 1901 with sheet steel spiders, is refuted by the record evidence of the catalogue — and also by the only actual specimen of that fan in evidence — Plaintiff's Exhibit 51.

But this is not all.

McBerty's statement is also definitely refuted by the testimony of the witness Binder, who was employed by Vallee Brothers of Philadelphia, sales agents for the Warren Company's fans during the year 1901 and later (Vol. I, pp. 384, 385), and who is therefore thoroughly familiar with the Warren Company's output, and who says of that company's 1901 fans (Vol. I, p. 386, Q. 16):

> "At that time I can say *the universal construction was to make the spider on which the blades were mounted of castings*, and that was subject to breakage, a certain chance of breaking the spiders. *In later years* that was changed to make these spiders of stamped metal.
>
> "*Q.* 17. Does what you have just said apply to the Peerless fans?
>
> *A.* Peerless fans and other fans also."

Not only, then, is McBerty's story that in 1901 the spiders of the G-type fans were made of sheet steel, and not of cast brass, contradicted by the record evidence furnished by the catalogues and by a sample of the fan itself, but it is definitely contradicted by the witness Binder, whose business it was at the time to know the construction of these fans, and to sell them.

The story is, moreover, extremely improbable when one considers the fact that the very purpose for which this G-type fan was gotten up was to produce a fan which

would be *less expensive* to manufacture than the others, and could be sold cheaper; whereas the change from a cast spider to a sheet steel spider would inevitably have caused a large increase of cost. Such a change would have required much new apparatus and new and expensive hand operations. By way of new apparatus, there would necessarily have been required, 1st, a die to stamp out the spiders; 2d, a die to punch the central hole in the spider and the rivet holes in its arms; 3d, mechanism for forming a steel hub and cutting a collar on it; 4th, an upsetting die for upsetting the projecting end of the hub over the spider to fasten it in place.

This would have involved also new manufacturing operations as follows: — 1st, the work of stamping out a spider; 2d, the work of punching the central hole in the spider; 3d, the lathe work necessary to shape the hub and cut away the collar on it, an extremely expensive operation unless special automatic machinery involving heavy expense was procured; 4th, upsetting the end of the hub of the spider so as to fasten the two parts together.

That the Warren Company should have substituted a sheet steel spider, involving all these operations and apparatus, for a simple cast metal part, in a new fan which they were getting out with the one object of *reducing cost* when they were making no such change in the rest of their output, would be so absurd that the story that it was done would be unbelievable, even if it were not definitely contradicted definitely in so many other ways.

The story is inconsistent with the excuse that McBerty gives for the abandonment of the alleged spot welding process, namely, that it would require the purchase of an additional welding machine, jigs, etc., which would have involved "added equipment" (Vol. II, p. 946) and "further expenditure" (Vol. II, p. 869).

Later on, in 1909 or thereabout, the Peerless Company,

successor o the Warren Company, adopted the sheet, metal spider on all its fans, and the McBerty Exhibit M, spuriously dated 1901, is doubtless composed of one of these spiders of 1909, or later, attached to a fan blade.

We submit, therefore, that the proposition advanced by McBerty that the G-type fans upon which his alleged work was done in 1901 had sheet steel spiders (a proposition absolutely necessary to his story) is positively disproved.

THE "CORROBORATING EVIDENCE" PRODUCED BY DEFENDANT TO SUPPORT McBERTY'S STORY ON ANALYSIS WHOLLY FAILS TO CORROBORATE IT.

The evidence produced by defendant to corroborate McBerty's story told in this case may be summarized under three heads: *first*, and foremost, the cut of the G-2 fan in the Warren Company's 1901 catalogue, which defendant alleges shows a fan with spot welded blades and spider, one of the "trayful", made by McBerty in 1901; *second*, the physical exhibits produced as contemporaneous specimens of McBerty's 1901 work, notably Exhibit M; and *third*, the oral testimony of other witnesses called to corroborate McBerty.

We shall take up these several points in order and show the Court that none of the three gives any support to McBerty's present story.

THE CUT OF THE G-2 FAN IN THE WARREN COMPANY'S 1901 CATALOGUE.

On page 17 of the Warren Company's 1901 catalogue (Defendant's Exhibit No. 2) appear two cuts, showing respectively the G-1 and the G-2 fans.

The defendant triumphantly points to the cut of the G-2 fan, saying that it does not show any rivet heads, and therefore claims that here is record evidence in support of

McBerty's contention as to the trayful of spot welded fan blades and spiders made in the year 1901.

Upon this cut, which was not referred to in the story told in 1913, to Mr. Howe or to McBerty's counsel, McGill, is largely built the defendant's case. As we shall see later, in collecting evidence for the defendant in this case this cut was shown by McBerty and by defendant's agent, Smith, to the witnesses who have testified for the defendant, with the assertion that it proved the spot welding contention; it has been used as a means of "refreshing" the memory of these witnesses, practically all of whom, as we shall later see, remembered nothing of the kind in 1913.

We point out in the first place that there is a discrepancy in the testimony of McBerty himself on this point, for he said in his answer to Q. 92, Vol. II, p. 724 (just before the catalogue was handed to him for identification by his counsel), that the alleged 1901 spot welding was done *"on the small fan,"* that is to say, on the 12-inch or G-1 fan shown at the left of the two cuts in the catalogue, as distinguished from the larger 16-inch G-2 fan shown at the right. *But rivet heads can be clearly seen on this small G-1 fan*, as McBerty admitted in his answer to Q. 95, page 725, so that the *small* or G-1 fan was certainly not spot welded as McBerty first testified. The witness Craft, whose recollection was "refreshed" by conversations with McBerty (p. 795, RXQ. 263), also stated that it was the small or G-1 fan that was spot welded (Vol. II, p. 792, X-Qs. 244–247).

It is not necessary, however, to enlarge upon this discrepancy, for there are more fundamental and absolutely unanswerable reasons why this cut fails to support the McBerty story.

The Catalogue is Proved by Defendant's Own Witnesses to Have Been Published at a Time Before McBerty Claims to Have Done or Could Have Done any Spot Welding.

It will be remembered that McBerty claims to have done his spot welding on these fan blades and spiders only in *February, 1901*, and says that this Exhibit M, which has stamped on it the date *February 15, 1901, was his first piece of work* (X-Qs. 425–429, Vol. II, p. 820.) We quote:

"*X-Q.* 425. How do you identify February as the month?

A. I identify February as the month on account of my first piece of work being produced, which was produced in February. . . .

X-Q. 427. That has stamped on it February 15, 1901, I believe?

A. Yes, sir.

X-Q. 428. Had you made any complete four-bladed fan blades at that time?

A. I think not. Otherwise it would not have been stamped as my first production along those lines.

X-Q. 429. Had you made any before that?

A. No."

Indeed, the butt welding machine on which McBerty claims to have done the spot welding was not put into use until after January 20, 1901, for it was on that date that the transformer was first turned over to the fan department of the Warren Company (Vol. I, p. 689).

These alleged spot welded G-2 fans, then, were certainly not made until after February 15, 1901. But defendant's witness Sawyer, who was called by defendant to identify this catalogue, says that it was **"undoubtedly published and printed in 1900, along in December, probably"**

(Vol. I, p. 682), that is to say, **some two months before McBerty on his own testimony ever spot welded a fan spider and blades.**

Mr. Estabrook, defendant's witness who produced his catalogue, explained that the fan season — that is, the period when the contracts for the sales of the fans are made — is January, February and March, and that the catalogues are gotten out *in preparation for that selling season* (Vol. I, p. 676). McBerty himself confirms this, saying (Q. 109, Vol. II, p. 728):

> "We issued one catalogue per year, and this was brought out sufficiently early to get in the hands of the jobbers *before the fan season started.*"

February, he says, was "late in the season" (Vol. II, p. 856, X-Q. 963).

In fact, the advertisement of the Warren Company in the Electrical Review for *November 21, 1900*, Plaintiff's Exhibit 53, page 12, indicates that the catalogue was ready or about to be ready as early as this date, November 21, 1900, for it says:

> "Peerless incandescent lamps, fan motors, transformers are made on honor, no disappointments when used, *send for catalogue*, prices right."

Such an invitation would hardly have been issued unless there were catalogues ready to be sent to inquirers.

It is therefore established by defendant's own witnesses, including McBerty himself, that this catalogue was issued at least as early as December, 1900, long before any spot welding could possibly have been done or is claimed to have been done by McBerty.

Defendant's witness Roberts (Vol. I, p. 693) produces a ledger entry dated March 19, 1901, of the R. W. Roberts Company which published some of the Warren Company's

catalogues, which entry he says was probably for the printing of this catalogue. This entry was not made, he says, *until after the last shipment of the issue was made*, and as the deliveries might well have been made piecemeal, this proves nothing as to the date when the catalogue was printed (p. 695). Indeed Roberts' testimony strongly corroborates that of the other witnesses, for it is obvious that there would not have been time between February 15 and March 19 for the experiments to be concluded, jigs made to hold the blades and spiders during welding, a complete fan to be assembled, japanned and photographed, a cut made from the photograph, and the work of printing and binding 3,000 to 5,000 catalogues (p. 693) done.

The evidence above stated as to the date of publication of this catalogue, which is obviously enough to demolish McBerty's pretensions as to the significance of the cut, stands, then, absolutely uncontradicted, and it comes from defendant's own witnesses.

The Catalogue Cut Shows a Riveted and Not a Rivetless Fan.

Even if the cut did not show rivet heads on the faces of the blades, no inference could be drawn that there were no rivets in the actual G-2 fan. Mr. Turner, a professional photographer, explains (Vol. I, p. 306) the manner in which such a cut is made. The original negative is treated with an "air brush" which may eliminate such details as rivet heads, and then the negative is retouched before the cut is made. In the retouching process an unimportant detail like a rivet head may or may not be restored by the photographer. This is illustrated by comparison of an original photograph of a riveted fan made by Mr. Turner (P. Ex. 34, Vol. I, p. 485) with a cut made from that photograph treated with an "air-brush" in the usual manner (P. Ex. 37, Vol. I, p. 487). The photograph clearly shows the rivets, but the cut shows none.

An examination of the other cuts in this catalogue of 1901 shows that rivet heads are sometimes not shown on admittedly riveted fans. See, for example, the cuts of the blades of the E-2, E-3 and G-1 fans in this 1901 catalogue, in some of which some of the rivet heads are lacking while in others they are shown. It may depend largely on the amount of light thrown on the fan blade. Thus in the cut of the G-1 (p. 17) fan three of the blades are comparatively unlighted and no rivets are seen, but in the portion of the fourth blade exposed to direct light they stand out clearly. No part of the blades in the G-2 cut appears to be exposed to a direct light.

McBerty explains the failure of the rivets to appear on some of fan blades in certain of these cuts by saying that the rivet "does not always show in the figure, depending upon the way the light strikes the fan blade" (Vol. II, p. 872, X-Q. 1205), an explanation which is entirely sufficient to account for the absence of any appearance of rivets on the faces of the fan blades in the G-2 cut.

Conclusive evidence that the absence of a showing of rivet heads on the faces of the blades is no proof that the blades were spot welded is furnished by the fact that the 1903 catalogue of the Colonial Fan Company, the selling agent of the Peerless Company (Sawyer, Vol. II, p. 1009), *shows two cuts of fans in neither of which are there shown any rivet heads on the blades* (McBerty, Vol. II, p. 1019). There is no suggestion or pretense that any 1903 fans were spot welded. On the contrary both McBerty (pp. 830, 831) and Smith (Vol. I, p. 520) state positively that no spot welding was done after 1901.

Some of the Warren Company's fan blades were countersunk so that the rivet head was flush with the front surface of the blade, the rivet projecting only behind the spider (Brewer, Vol. I, p. 287, Q. 32); and here again is a

reason why the rivets, when the blades were covered with a coat of japan, might not show in a photograph, or be noticed by a casual observer.

The mere fact, therefore, that a cut of a fan shows no rivet heads on the blades is not proof by any means that such blades were spot welded.

But as a matter of fact, while no rivet heads are to be seen on the *faces* of the blades in the cut of the G-2 fan on page 17 of the 1901 catalogue, *a rivet head does indistinctly appear upon the rear side of the downwardly extending blade* (Wagner, Vol. I, p. 344; Gravell, Vol. I, p. 322), as careful examination of the cut will show. Although McBerty was called twice in sur-rebuttal he did not venture to deny the testimony of plaintiff's witnesses to this effect.

In working up the McBerty story for the purposes of this case photographs of this misleading cut were taken about by the defendant's investigator and witness, Mr. W. E. Smith, by McBerty, who interviewed the other witnesses, and by defendant's counsel,* and they, with 1917 photographs of the welder, Exhibit B, in the process of spot welding a fan blade to a spider, were undoubtedly used to convince witnesses, whose own personal recollection was lacking, that fans with spot welded blades were manufactured by the Warren Company in 1901.

But the fact is that the catalogue illustration could not possibly show a spot welded fan sold by the Warren Company, because it was printed and published at a time before any spot welding could possibly have been done or is claimed to have been done by McBerty and that *the catalogue illustration does not show a rivetless fan at all.*

*Such photographs are in evidence in Plaintiff's Exhibits No. 38 and No. 39, which were shown by W. E. Smith to L. C. Brewer, the regular operator of the machine from 1901-1904, in an unsuccessful effort to persuade Brewer to remember spot welding (Vol. I p. 275).

THE EXHIBITS IN EVIDENCE PURPORTING TO BE SPECIMENS OF McBERTY'S 1901 WORK.

Exhibit H.

The only specimen purporting to represent McBerty's 1901 work in the case, which is identified by any other witness than McBerty himself, is Exhibit H attached to Lipps' affidavit of 1913, put in evidence by plaintiff. As proved by Lipps' time book, his first acquaintance with McBerty's work was after April 29, 1901 (Vol. I, p. 451). This exhibit H consists of a pair of halves of thin steel armature lamination discs stuck together. Lipps states in his affidavit that it has been in his possession ever since it was made in 1901, and that he saved it "*as a kind of a sample*" of McBerty's 1901 experiments (Vol. I, p. 453).

This exhibit may be authentic, *but it is not spot welding.* It is what is known as a "stick" (Gravell, Vol. I, p. 323; Wagner, p. 345), and is exactly what would result from an attempt to weld with a current of only about one volt, which was the maximum pressure of the welding circuit that the 1901 transformer was capable of supplying. A "stick" results from the mere fusing of the oxides on the surfaces of the metal pieces and is to be sharply distinguished from a real spot weld, in which the metal in the body of the metal pieces fuses and merges (Vol. I, p. 369). No one would assert that Exhibit H is a specimen of real spot welding. *But Exhibit H represents the nearest approach to spot welding that could have been done on the machine equipped with the transformer which McBerty had in 1901 when supplied with the primary current of 250 volts used by the Warren Company.*

Exhibit H is a piece of most convincing evidence against McBerty's claims. Lipps naturally would have preserved as good a sample of McBerty's experimentation as there was, if he preserved any at all. That he

produced nothing better than this useless "stick" is most persuasive proof that McBerty produced no real spot-welds.

Defendant's counsel very significantly failed to ask Lipps anything about Exhibit H, and it was reserved for the plaintiff to put it in evidence along with Lipps' affidavit.

McBerty's Newly Produced Specimen, Defendant's Exhibit M, is Spurious.

We have previously pointed out that Mr. Edwards, counsel for the defendant in the Barney & Berry case, after examining the affidavits and evidence collected by Mr. Howe in 1913 and after talking with McBerty, concluded that it was useless to rely upon the alleged McBerty prior use, as well because it was not proved as because at best it amounted only to an abandoned experiment. There was *no record evidence* in support of the story, such as is necessary in order to comply with the established principles of law regarding the proof of prior use.

We have above shown that in the effort to avoid the criticism of "abandoned experiment" McBerty has now enlarged his story by telling about a trayful of fan blades and spiders which he asserts he spot welded and which he says went into the commercial output; and we have shown that that addition to his story is untrue.

We now shall deal with the second new addition to the McBerty story, which he has for the first time brought forward in this case and by which he hopes to supply the element of contemporaneous dated evidence, previously lacking. That is his Exhibit M, which he now produces as a specimen of his work done in February, 1901, and contemporaneously dated. It consists of a piece of spider made of sheet steel, spot welded to a fragment of a steel

fan blade which is nickel plated. The exhibit is stamped with the date "2–15–01" and with McBerty's name.

McBerty's statement as to this exhibit is absolutely uncorroborated. The exhibit is not identified by any other witness in this case.

The exhibit was certainly very new in appearance for an article made 18 years before it was introduced in evidence and kept loosely in a tool box ever since, and the marking on it might have been done yesterday. The exhibit is, we confidently submit, of recent origin, and McBerty's testimony regarding it is not the truth.

In the first place, the spider is of steel, whereas as we have shown in a previous section (p. 165), there were no steel spiders available to McBerty in 1901, but only in subsequent years. They are shown first in the Peerless advertising matter in 1909.

In the second place, the blade is copper-and-nickel plated (Vol. I, p. 346, Q. 16); but the G-1 and G-2 fans were the only ones made by the Warren Company in 1901 with blades not made of brass (Vol. II, p. 712), and the blades of the G-1 and G-2 fans *were finished in plain black enamel.* This is definitely proved by the description of these fans on page 17 of the 1901 Warren Company Catalogue, Defendant's Exhibit 2 containing the cuts upon which defendant places so much reliance. This catalogue description reads as follows:

> "Types G-1 and G-2 are rigid iron-clad fans of symmetrical design and strong mechanical construction. *The finish throughout is plain black enamel.*"

The fact that the 1901 steel fan blades were finished in black enamel is corroborated by defendant's witness Craft (X-Q. 229, Vol. II, p. 790), and by the sample of this 1901 G type of fan (Plaintiff's Exhibit No. 51) which we located and produced in evidence by the witness Binder

(Vol. I, p. 385); nor is it denied by McBerty or any other witness.

The truth is that in 1901 there were no nickel-plated steel blades.

In 1902 a change was made in the finish of the blades for the G-1 and G-2 fans, and in that year they were nickel plated. The legend at the foot of the cuts of these fans shown in the Peerless Company's 1902 catalogue (Defendant's Exhibit I) at page 11, shows this, and McBerty admits that this change was made in 1902 (p. 728, Qs. 113, 114). He testifies as to this change (Q. 114, p. 728):

> "Instead of supplying a black japan finish over the entire fan, they have changed the finish from black japan to nickel plate as far as the guards and the blades are concerned."

It was not until at least 1902, then, that any nickel-plated fan blades were available to McBerty.

Careful inspection of this Exhibit M furthermore, shows the marks of rivet heads about the rivet holes (Gravell, Vol. I, p. 324, Q. 22; Wagner, p. 346). This means that the blade had at some time been riveted and that the rivets were taken out and the blade spot welded to the spider arm. All the circumstances indicate that McBerty made this exhibit at some comparatively recent time by removing the rivets from an old fan blade and spot welding the blade to a modern sheet steel spider arm. But when he did it *he forgot that there were no such nickel-plated fan blades in 1901.*

Equally convincing evidence that Exhibit M is spurious is the fact that McBerty, who says that he found this exhibit in his tool box in 1911 (*supra*, p. 146) never showed it either to his attorney, Mr. McGill, who made a thorough investigation of the subject-matter in the early part of

1913, or to Mr. Howe, who, in the latter part of 1913, spent two weeks with him in investigating the story, getting affidavits of numerous witnesses, including McBerty himself, and collecting evidence for use in the Barney & Berry case. It was just this kind of dated evidence that these attorneys were looking for. Mr. Howe particularly testifies how keenly alive he was to the necessity of having some such evidence (*supra*, p. 144).

McBerty's letter to his attorney, Mr. McGill, of January 2, 1913 (dated January 2, 1912, by mistake), said (Vol. II, p. 945):—

> "I have also samples of spot welding which was done on the welder at the time we did this experimenting, and while *we are unable to identify the exact date* we can approximate it within two or three months."

McBerty's statement to Mr. McGill that he had no means of identifying the exact date of his experimenting is utterly inconsistent with his possession at that time of this dated specimen. McBerty's statement that he deliberately held the specimen back from Mr. Howe (Vol. II, p. 843, X-Q. 841) is wholly incredible in view of the weeks of time and effort that he put into collecting evidence for Mr. Howe and of what McBerty had at stake.

It is putting the matter mildly indeed to say that Exhibit M is not proved by that degree of evidence which is requisite for prior use testimony.

We go so far as to say that in all probability this McBerty Exhibit M was fabricated after April, 1918, when McBerty's corroborating witness, William E. Smith, testified. It is only reasonable to suppose that had this Exhibit M been in existence at the time of Smith's testimony, he would have known about it and testified concerning it. Smith's silence as to this exhibit in his testi-

mony of April, 1918, strongly indicates its non-existence at that time.

Other Specimens of McBerty's Alleged 1901 Work.

In connection with the affidavits which were obtained by Mr. Howe in 1913 from McBerty, Lipps and Brown, there were produced four physical exhibits, namely, Exhibits O and P attached to McBerty's affidavit, Exhibit H attached to Lipps' affidavit, and Exhibit B attached to Brown's affidavit. These exhibits — the only ones in the case except Exhibit M — further discredit McBerty's story of 1901 spot welding.

Exhibit H we have already mentioned. It is produced and identified by Lipps as having been in his possession since some date in 1901 after April 29.

It is a mere "stick" such as might well have been made with the machine and transformer as it was in 1901. It is in no sense an example of successful spot welding, and no one asserts that it is.

Exhibit B, attached to Brown's affidavit, was not produced as a 1901 sample, for Brown in his affidavit merely said that it was like what he saw in 1901 (Vol. I, p. 481). McBerty's affidavit says nothing about this sample, and its origin is wholly unexplained. No reference is made to it in the testimony in this case.

Exhibit O and Exhibit P are two specimens produced by McBerty in connection with his affidavit of 1913. McBerty there alleged that these were made in 1901. *He makes no such assertion in his present testimony* for the good reason that they could not have been made in 1901.

Defendant did not even offer these exhibits in evidence in this case. McBerty was not questioned about them except in connection with his cross-examination. They were put in evidence by plaintiff together with the McBerty 1913 affidavit.

Each of these two exhibits is made from a piece of a steel spider and a piece of fan blade. But there were no steel spiders available to McBerty in 1901 (*supra*, p. 165). The fan blade of Exhibit O is made of steel which is copper plated and oxidized (Wagner, Vol. I, p. 345), and that of Exhibit P is made of steel which is copper and nickel plated. But there were no fan blades of steel which were copper plated and oxidized or copper and nickel plated available to McBerty in 1901; *the only steel blades which the Warren Company had in that year were finished in black enamel*, as we have pointed out above, p. 179.*

*Exhibit P is closely related in origin, evidently, to Defendant's Exhibit M, upon which McBerty now places such reliance. It will be remembered that Exhibit M is the specimen produced by him in this case for the first time, bearing the date stamped on it "2-15-01" and McBerty's name, this being the sample which now turns up for the first time and which he never showed or mentioned either to Mr. Howe or to his own attorney, Mr. McGill and to which he did not refer in his affidavit of 1913. The piece of a spider included in Exhibit P was evidently cut off from the piece of spider included in Defendant's Exhibit M, since the two parts fit together.

McBerty asserted on the stand that when he put the story up to his attorney, Mr. McGill, early in 1913, he cut the sample of his work which he then had in two, keeping one part of it and giving Mr. McGill the other part, and that this other part which he gave to Mr. McGill was what he showed Mr. Fish at his interview in 1913 (Q. 179, Vol. II, p. 738; Q. 182, p. 739; pp. 267, 268); and he says Exhibit M is the part which he retained and which never left his possession (Q. 150, Vol. II, p. 733; Q. 154, p. 735; Q. 254, p. 753). Apparently this Exhibit P is what McBerty had in mind in this testimony, for the sample which he gave Mr. McGill and which was turned over to Mr. Edwards was annexed to his affidavit prepared by Mr. Howe (Edwards, Q. 10, Vol. I, p. 291; Q. 11, p. 292). At all events these samples annexed to the affidavits are the only ones which we know anything about. McBerty's story is very much mixed, for the Exhibit P, while its spider part was evidently cut from the spider part of Exhibit M, does not match up with Exhibit M in the way in which McBerty said that it should.

McBerty admits that Exhibit P was not made at the same time as Exhibit M and not until long after, because he says that the piece which has been cut from the fan blade of Exhibit M and which he says appears in Exhibit" P was not cut off from Exhibit M until "quite a long while" after the fan blade of Exhibit M was welded to the spider (Q. 258, Vol. II, p. 754).

The blade of Exhibit O has been welded to the piece of spider arm *after* the spider arm was cut off from the rest of the spider, as shown by the blueing or heat marks on the cut surface of the spider arm caused by its oxidizing in the air when the blade was heated in welding (Gravell, Vol. I, p. 323, Q. 15, 16).

Concentric marks around the two rivet holes in the blade of this exhibit show that it was once riveted (Gravell, Q. 17).

The cut end of the spider arm of Exhibit P shows the same blueing as in the case of Exhibit O, and indicates that this exhibit also was welded *after* the spider arm was cut (Gravell, Q. 19).

The indentations on the backs of the welds of Exhibits O and P are perpendicular to the surface. If they had been made on blades attached to a spider the indentations would have been slightly oblique because the spider with blades attached would have to be put into the machine at a slight angle, as was demonstrated in the operation of the machine at the Ford plant (Gravell, Q. 27–29).

The evidence afforded by these exhibits themselves shows, therefore, that they could not have been welded in 1901 because neither blades so finished nor sheet steel spiders were available in that year.

The heat marks of the welding that appear on the surface of the cuts show that the spider arms were cut before the blades were welded to them. This completely refutes McBerty's assertion that he welded these blades to a spider which was afterwards cut into pieces.

That these exhibits were probably welded some time after 1909 is shown by the fact that no such sheet steel spiders were in existence at the Peerless plant before that year.

These two exhibits P and O are not vouched for by any witness whatever in the present case; even McBerty appears to rely upon them no longer, for, as we have said,

they were not mentioned by him except in connection with his cross-examination.

The upshot of the whole situation, then, so far as the exhibit specimens are concerned, is that there is no single exhibit purporting to have been made in 1901 which is identified by anyone but McBerty himself except Exhibit H, the "stick" produced by Lipps which is not spot welded at all; that McBerty no longer relies upon or testifies about any exhibit other than Exhibit M, the dated specimen which turns up for the first time in this case, and that Exhibit M, like the other specimens except Exhibit H, bears on its face evidence that it could not have been made in 1901.

THE "CORROBORATING" WITNESSES.

We have shown that there is nothing whatever in the nature of *record evidence* to support McBerty's story — none of the "*concrete, visible contemporaneous proofs which speak for themselves*" which experienced courts require to support a prior use contention (*Emerson & Norris Company* v. *Simpson Bros.*, 202 Fed. 747, C.C.A. First).

The machine, *Exhibit B*, we have shown, *supra* p. 150, to be nothing but a mere recent reconstruction embodying certain parts only of the old 1901 butt-welding machine, and mounted in a vitally different manner from that in which the 1901 butt-welding machine was mounted; and its alleged similarity to the 1901 machine depends absolutely upon oral testimony, and at that upon the oral testimony of McBerty alone, contradicted by some half dozen thoroughly reputable and disinterested witnesses, called by the plaintiff as well as by a number of witnesses of the defendant.

No *specimen of a fan having spot welded blades*, such as McBerty claims that the Warren Company sold, to the number of a dozen or fifteen, is produced, although defendant says that it has spent much money and effort in the

attempt to locate such a specimen. It is likely that if there ever had been a dozen such fans made it would be possible to produce at least one, as a result of all this search.*

The *catalogue cut* of the G-2 fan which is so much relied upon in support of McBerty's contention is shown to be no support at all, for the catalogue is proved by defendant's own witnesses to have been published months before McBerty claims to have done his work, and even before the machine on which he claims to have done the work was installed; and, moreover, it does not show a rivetless, but a riveted, fan.

There is nothing in the nature of a *contemporaneous specimen of McBerty's alleged 1901 spot welding work in evidence that is identified by any other witness than McBerty himself, except Exhibit H*, produced by Lipps, which he could not have seen made till after April 29, 1901, and

*Defendant has found numerous fans of the G type in question (Vol. II, p. 760), but has nof produced one of them. We ourselves have located and put in evidence one such fan (P. Ex. 51; Vol. I, p. 382). *None of these had spot welded blades.*

No such spot welded fan has been produced — for the reason that *no spot welded fan ever existed.*

The story by defendant's witness, Ensor, that he saw a fan with rivetless blades in the junk room of the Peerless Company in 1911 is merely uncorroborated memory and of course a fan which appeared for the first time in 1911 is utterly of no consequence. It was in the Peerless junk room that McBerty in the same year, 1911, found parts of his old welder and transformer (Vol. II, p. 832). If there had been in that room in 1911 a fan with blades spot welded by him in 1901, it is impossible that he should not have found it and kept it as pretended proof of his alleged 1901 spot welding.

Defendant's witness, McDonald, who remained with the company for years, asserts particularly that no spot welded fan ever came back and therefore none could have been in the stock room, where returned fans were kept (Vol. II, p. 882, Q. 63).

McBerty also made a thorough search for a spot welded fan or such a "fan blade independent of the motor" in the plant of the Peerless Company in 1913 (Vol. II, p. 961, Q. 7), but he did not find any such thing.

therefore contradicts McBerty's story of successful spot welding in February, 1901. This exhibit is a mere "stick", not a true spot weld at all, and not pretended to be such by the defendant. By itself it goes very far to prove that McBerty's experiments in 1901 did not produce successful spot welding, for otherwise Lipps would have preserved a sample of such welding instead of this unsuccessful "stick". Exhibit M, the dated specimen now produced by McBerty, but identified by no other witness, is clearly shown to be spurious, — manufactured as we believe for the purposes of this case, and at any rate a recent construction.

There were, however, a number of witnesses called by the defendant who, speaking purely from memory nearly eighteen years after the event, and after having their memories artificially "refreshed" by being shown the misleading catalogue cut of the G-2 fan, the reconstructed and changed Exhibit B, and alleged samples of spot welding done on it, purport to give testimony in corroboration of some parts of McBerty's story.

McBerty himself is clearly discredited as a witness, That circumstance goes far towards overthrowing the entire prior use story. He is the mainstay of the defense. the central prop of the entire fabric. In all the cases of a discredited attempt to defeat a patent by an alleged prior use, the courts have recognized that if the story of the man whose work is relied upon is false, the testimony of those who are merely called to corroborate him is subject to suspicion. The courts know how easy it is to excite in such corroborating witnesses a recollection of facts that, never existed, particularly if they are skillfully approached with such significant refreshers of their memories as the cut in the 1901 catalogue and the reconstructed machine Exhibit B. In many such cases the controlling circumstance has been the breaking down of the story of the

main witness. If his testimony is shown to be false or ineffective, the rest of the case should in almost every instance fall with it. In many cases distrust of the main witness has largely contributed to disbelief in the whole story.

In the *Telephone Cases* (126 U.S. 1) not one only but several men, after Bell's patent came out, claimed that they had made the invention years before. Drawbaugh was one of these alleged prior users, and he supported his claims by *not less than two hundred witnesses* who swore in court that they were familiar with his telephone many years before Bell's invention was made. The court, however, recognized that it was simply impossible that anyone could have achieved Bell's result so many years before and have done no more about it than Drawbaugh did. The court said (p. 567):—

> "We do not doubt that Drawbaugh may have conceived the idea that speech could be transmitted to a distance by means of electricity, and that he was experimenting on that subject, *but to hold that he had discovered the art of doing it before Bell did would be to construe testimony without regard to 'the ordinary laws that govern human conduct.'* "

In another of the telephone cases, namely, *American Bell Telephone Co.* v. *American Cushman Telephone Co.*, 35 Fed. 734, another prior use was urged and supported by the testimony of a number of witnesses whose honesty the court (Judge Blodgett) did not question. The court, however, concluded that Cushman's imagination had been made morbidly active by seeing the fame and success of Bell, and that he had "clothed what he did in those past years with a light reflected from the success of others, and his statements of what he did then have unconsciously

colored the testimony of many of those he has called to support him".

In the Edison Incandescent Lamp cases, after the patent had been sustained in a hard-fought litigation, the patentee was confronted with an alleged prior use of one Goebel, whose story was corroborated by *not less than 40 witnesses.* Here again, as in the case at bar, the facts relating to the alleged prior use had been investigated by the defendant in the first case, and the defense found insufficient. It was rejected as inherently improbable in *Edison Electric Light Co.* v. *Beacon Vacuum Pump etc. Co.*, 54 Fed. 678, 692, Circuit Court District of Mass., and in *Electric Mfg. Co.* v. *Edison Electric Light Co.*, 61 Fed. 834, C. C. A. 7th Circuit.

In the case at bar there is not only the same inherent improbability of successful prior use as in the *Telephone* and the *Incandescent Lamp* cases, but there are proved by competent evidence, mainly supplied by defendant's own witnesses, a number of facts which convert that improbability into an impossibility. These facts not only contradict McBerty in every important circumstance relating to his alleged prior use of spot welding in 1901, but also explain how the witnesses called to corroborate McBerty were misled by him and by his fabricated evidence, including apparently authentic but really false and misleading photographs of his welding machine the deceptive and misleading cut of the G-2 fan in the 1901 catalog, and of its supposed 1901 spot welding product, and samples of spot welding alleged by him to have been made in 1901 but now proved to have been made of blades and spiders which did not exist in that year.

While we cannot believe it to be necessary, we will briefly analyze this memory evidence—given *eighteen years* after the event—upon which defendant must rely, to substantiate McBerty's story.

The alleged corroborating witnesses, who testify for defendant in this case, are Craft, Powers, Gilder, McDonald, Lipps and Smith.

Powers and Lipps.

As to the witnesses Powers and Lipps, there is nothing whatever in their testimony inconsistent with our proposition that what McBerty did was an abandoned experiment. Both of these men say that what McBerty did was purely experimental. "They were not going through the commercial part of it"; "Just experimental" (Lipps, Vol. II, p. 923, X-Qs. 83–85).

Powers says that "all of the spot welding that I can recall was experimental" and he never saw any complete fan blades and spiders spot welded by McBerty (Vol. II, Q. 35, p. 875; Q. 39, p. 876). The exhibit produced by Lipps, "Exhibit H", as a sample of the work that McBerty did in 1901, even assuming that it is authentic, is nothing but a mere "stick". It is not spot welded at all, and is just the kind of work that might have been done with a transformer of the small capacity which McBerty's transformer had in 1901 which could not supply adequate current to make a spot weld.

Craft, McDonald and Gilder.

Each of these witnesses was interviewed in 1913 by Mr. Howe, in company with McBerty, and *each and every one of them at that time, which was six years nearer the date of the circumstances as to which they were testifying, had little or no recollection of the alleged spot welding about which they now glibly testify.*

Craft, when interviewed in 1913 by Mr. Howe and asked for his recollection regarding the matter, said that he did not recollect the matter very much and refused to give a affidavit (Howe, Vol. I, p. 304, Qs. 16–18). Craft himself admits that

"I told him I was hazy about this spot welding, and **I didn't feel as I remembered it then that I could possibly state about the spot welding end of it." . .**

"I had forgotten the whole circumstances for several years, of course." (RX-Qs. 262–264, Vol. II, p. 795.)

Craft even now admits that he *never saw any spot welding* (Vol. II, X-Q. 87, p. 780); he merely says that he *was told by McBerty* that some fans that were shown to him were "spot welded".

McDonald likewise was interviewed by Howe in 1913 and "did not seem to have much recollection in regard to the early welding" (Howe, Vol. I, p. 301), although McBerty and Howe "used every effort to stimulate his recollection by suggesting things" (Howe, Vol. I, p. 378, Q. 7). At that time, as McDonald admits, he **"didn't recall distinctly"** the things to which he now testifies (McDonald, Vol. II, X-Q. 78, p. 883). An affidavit was drawn up by Howe for McDonald's signature, which affidavit was forwarded by him to McBerty but never sworn to. *That affidavit McBerty never delivered to Mr. Howe, and it has been suppressed: at least McBerty does not now produce it* (Howe, Vol. I, Qs. 8, 9, p. 379; McBerty, Vol. II, X-Q. 11, p. 971).

Gilder also made an affidavit for Mr. Howe in 1913, in which affidavit (see Plaintiff's Exhibit 29, Vol. I, p. 449) he said:

"The only kind of welding which I remember seeing done on the machine at that time was the welding together of the ends of the stock to make the fan guard rings. [This was butt welding.] It was only occasionally, however, that I was in a position to know what kind of work was being done on the machine, so that other kinds of work and

characters of welds may have been made which I knew nothing about."

Now, under the stimulus of the effective coaching of Smith, McBerty and others, Gilder says that he remembers seeing some fan blades, which had been electrically welded on this machine, in a tray (Vol. II, p. 904). But *he did not see the process.* He did not know of his own knowledge how the blades and spiders were put together.

Such testimony as that of Craft, McDonald and Gilder, in view of their complete lack of knowledge of the subject-matter six years before the date of their testimony (and six years nearer to the time when it all was supposed to have happened), ought, we submit, to carry no weight at all.

Smith.

The other witness, Smith, is the man who was hired by the "Welding Patents Investigating Committee" in 1917 to line up witnesses and work up the evidence regarding this McBerty alleged prior use. Although Smith was living in Warren in 1913 when McBerty spent two weeks of his time taking Mr. Howe around to see all possible witnesses who could be found to support his story, McBerty never thought it worth while to take Howe to see Smith (Vol. II, p. 860, X-Q. 1046; Vol. I, p. 514, X-Qs. 262–265). He thought of Smith as a "transformer man" (p. 863, X-Q. 1100) and evidently did not expect him to know anything about the welding work.

Smith's memory has now been "refreshed" by the cut of the G-2 fan in the 1901 catalogue of the Warren Company (RDQs. 380-382, Vol. I, pp. 523, 524), which has been used to "refresh" the memory of the other witnesses and to make them believe that it represents spot welded fan blades when in fact it shows nothing of the kind.

Smith, now in his paid enthusiasm to support McBerty's story, goes a little too far, for he says that he saw E. C.

Lipps using the machine for welding the blades to the spiders of fans (X-Q. 331, Vol. I, p. 520), and he says explicitly that it was in the latter part of January or in February of 1901 that he saw him doing this, and in no other months of that year and at no other time (X-Qs. 336–338). But Lipps never went to the Warren Company factory after the welding machine was installed until after he left his job at Cleveland on April 29, 1901 (see his affidavit, Vol. I, p. 451). He does not recollect even that he ever saw the process of welding the fan blades (Q. 17, Vol. II, p. 917), much less did he ever carry on that process himself.

Many Witnesses, Familiar with the 1901 Butt Welding Machine, Never Heard of its Being Used for Spot Welding.

As against this contradictory and artificially "refreshed" recollection testimony we have the unequivocal testimony of many witnesses, employees of the Warren Company at the period in question, to the effect that they never knew of this machine being used for anything but butt welding. This is the testimony of L. C. Brewer, the regular operator on the machine from the time it was put in and for four years thereafter (Vol. I, p. 270, Qs. 15, 16; p. 274 Q. 52); of C. R. Brewer, who was employed in the fan department at the time and saw the machine every day (Vol. I, p. 285, Qs. 14–16; p. 286, Q. 24); of C. J. Wolfe, who helped make the welding machine and whose job it was to assemble the fan motors (Vol. I, pp. 309, 310, Qs. 8–11; p. 311, Q. 18); of George I. Spade, who was an assembler in the fan department and frequently saw the machine (Vol. I, p. 314, Qs. 12–16; p. 315, Qs. 24, 25); and of L. L. Little, who assisted in making the machine and getting it going (Vol. I, p. 311, Qs. 8–10; p. 280, Qs. 17–19). There are also the affidavits to the same effect obtained by Mr. Howe

with McBerty's knowledge and assistance, of the following: Robert J. Meenely, whose work was to make the fan guards that were welded on this machine (Vol. I, pp. 465, 466); Walter T. Wakefield, who was in charge of the japanning department which japanned these fans (Vol. I, pp. 468, 469); David R. Estabrook, now superintendent of the Peerless Company (Vol. I, pp. 469, 470); Robert W. Bean, the machinist who assisted in making the copper jaws for this welding machine (Vol. I, pp. 470, 471); Alfred C. Ulp, who sometimes assisted in butt welding on the machine (Vol. I, p. 474); and Alton J. Lewis, a machinist then and ever since in the employ of the Warren Company and its successors (Vol. I, pp. 476, 477).

None of these affiants ever saw or knew about spot welding in the factory of the Warren Company, certainly not in 1901, although they were employed there and some of them at least would have known of the matter if there were any real foundation for McBerty's story

No One Claims to Have Actually Seen McBerty Weld the "Trayful" of Fan Blades and Spiders.

Even Smith, who was hired by the Welding Patents Investigating Committee to work up this McBerty defense, carefully avoids stating that he saw McBerty actually welding four blades to a spider. He says he saw at least a dozen, perhaps more, "completed fans" "so welded" (Vol. II, p. 496, Q. 47). Completed fans are those which were ready for the market and therefore had been japanned or black enameled. The black enameling on the faces of the blade would conceal the heads of countersunk rivets, which might have been employed to give a smooth finish to the faces of the blades.

Craft did not see McBerty do any spot welding (Vol. II, p. 780, X-Q. 87). He only saw the front of the blades

after they were japanned (p. 790 X-Q. 228–229). So that if the rivet heads were countersunk and then japanned he would not have seen the rivets (X-Q. 230–232). It is merely an "inference" on his part that the fans were spot welded (X-Q. 233).

Powers, who "installed a piece of fiber insulation the full length of the machine which is different from the one now in place" (Vol. II, p. 874, Q. 18), only saw what he calls "experimental work" on transformer iron and fan blade stock (Q. 35–38). He did not "see any complete fan blades with the spiders" (Q. 39).

McDonald (whose testimony, as we have shown, is completely discredited by his non-recollection when seen by Howe and McBerty in 1913; *supra*, p. 191), now, after evident coaching by McBerty, states that he saw McBerty weld four blades to *one* spider (Vol. II, p. 881, Q. 37–39). No one else ever claims to have seen as much as that.

Gilder never saw anyone do any spot welding on the machine (Vol. II, p. 904, Q. 40).

Lipps doesn't recollect of seeing the fan blades themselves welded (Vol. II, p. 917, Q. 17).

Bettiker (Vol. II, p. 978) does not state that he saw any spot welding done.

The essential part of McBerty's story, therefore, namely, the fact that he spot welded a dozen or fifteen fan spiders to their blades, and that these spot welded structures went into complete fans that were sold, lacks even nominal corroboration from any witness.

Nevertheless some of these witnesses, — whose honesty we have no desire to question, — do claim to have seen in 1901 one or more fans with spot welded spiders and blades which McBerty told them he had produced. Their testimony cannot be true, for as we have shown above, it was, for a number of irrefutable reasons, impossible for McBerty to have spot welded these structures in 1901

when he says he did. How, then, is this testimony to be explained? We respectfully submit that there is no burden upon us to explain this matter; the failure of the McBerty defense is clear; but we venture to suggest a possible explanation.

The Possible Actual Facts in the Matter.

There is no doubt that McBerty set up in the Warren Company factory early in 1901 a welding machine having some of the parts of the machine in evidence as Exhibit B, and that this machine was subsequently used for the purpose of butt welding the ends of the fan guard rings for the new G type fans. The machine was not, however, in its present condition. As we have shown above, it had no space for welding a fan spider and blades, and the maximum potential which the transformer would deliver was only one volt, which was insufficient to do spot welding, and hardly sufficient for butt welding.

McBerty may have done some experimenting with this machine. Craft testifies:—

> "We did do almost all sorts of experimenting on that machine. We tried most everything." (X-Q. 184, Vol. II, p. 787.)

And it is possible that in the course of that experimenting McBerty tried to see what would happen if he interposed two thin sheets of steel between the ends of two copper wires placed in the clamps of the machine. It is not worth while for us to question the authenticity of Lipp's Exhibit H (the only exhibit in the case purporting to represent McBerty's 1901 work which is vouched for by anyone except McBerty himself). This Exhibit H is a mere "stick" showing on its face that sufficient current was not used to do real spot welding. Exhibit H is made of a pair of pieces of armature laminations, but it may even

be that McBerty also tried the operation with similar results on pieces of fan blades lying above the plant. *That was all that he did or could have done in any way relating to spot welding on this machine.* Even this much is not proved. Such experimenting which McBerty may have done may furnish the ground-work upon which the testimony of the other witnesses is based, and from which, by skilful coaching, has been developed, after 18 years lapse of time, the present greatly enlarged story. There is nothing surprising about this growth of the story. It is because of their recognition of the fact that such stories do grow in this way, that the courts have laid down the salutary rule requiring that an anticipation of this sort should be proved "beyond a reasonable doubt" and that something more than memory evidence is necessary to prove such an alleged prior use (authorities, *infra*, p. 200).

We have seen that no witness claims actually to have seen McBerty spot weld the blades to the spiders of his trayful of fan blades and spiders. But a few of them do claim to have seen completed fans that had been spot welded. This erroneous impression on the part of these witnesses, if it has any basis whatever, may well have been due to the fact that in some of the Warren Company's fans the heads of the rivets were *countersunk* in order to provide a flat surface for the japanning in which case the rivet heads would not show. Thus Brewer testifies (Vol. I, p. 287, Q. 32) that in some of the fans at some time "the blades were countersunk and a flush rivet was inserted and the head was riveted on the back of the spider". When the blades of these fans were japanned, as they were in the G type fans, they would look as spot welded blades now look, because no rivet heads were to be seen.

The Testimony of Defendant's Witnesses was Falsely "Refreshed" by Showing them the Misleading Catalogue Cut and the Reconstructed Exhibit B.

The testimony of the defendant's witnesses shows very clearly how their recollections were falsely stimulated by the misleading interpretation of the cut of the G-2 fan in the 1901 catalogue of the Warren Company, used by Mr. McBerty to embellish his story of spot welding.

McBerty apparently had sufficient recollection of the 1913 affidavits collected by himself and Howe to know that Lipps and Brown, the men on whom he relied in 1913 to corroborate his statements, had stated in their affidavits that there was never any actual practical or commercial use of McBerty's 1901 spot welding and he therefore ignored them and sought first his friend, William E. Smith, whose affidavit had not been taken by Mr. Howe, although Smith was living in Warren in 1913, when Howe was there and was readily available to give an affidavit had he known anything about the 1901 alleged spot welding.

Armed with the photograph, superficially authentic, of the G-2 alleged spot-welded fan in the 1901 catalogue, and with the welding device of Exhibit B rearranged so as to protrude sufficiently from the edge of the bench to permit the insertion of a fan spider and four blades, and connected to a modern transformer capable of providing a current adequate for spot welding, McBerty in 1917 could easily make a demonstration to Smith of spot welding of the kind which he desired Smith to remember as having been done in 1901. Smith could be induced to swallow the story, hook, bait and sinker, since his own recollection of the actual facts had been dimmed by the lapse of sixteen years, and since it was to his interest, as the paid investigator for the Welding Patents Investigating Committee,

to remember the facts as McBerty told them. Smith then set out to hunt up witnesses and to persuade them also of the truth of the story. He, of course, took with him the same cut of the G-2 supposedly rivetless fan, and photographs of the McBerty remodeled machine with fan blades and spiders in welding position (such as he showed L. C. Brewer; see Plaintiff's Exhibits 38 and 39, offered Vol. I, p. 308), and undoubtedly also showed the witnesses samples of complete fan blades and spiders which he represented, on McBerty's say-so, to be exactly like the work said to have been done in 1901.

It is therefore not surprising that out of the many ordinary workmen who were employed by the Warren Electric & Specialty Company in 1901, and who saw the machine butt welding, and perhaps used, as Craft says, in experimenting in other ways (possibly even in an attempt to "stick" with electrodes), there could be found some whose recollections were sufficiently obliterated by time so as to be capable of receiving a fresh impression from the plausible story of McBerty and Smith, backed by plausibly presented photographs of an alleged actual spot welded fan, and who would therefore adopt the story told by McBerty and Smith.

When such men had once been persuaded to accept McBerty's story of actual practical spot welding for commercial fans in 1901, all the rest of the details followed as a matter of course and the minds of these witnesses naturally imported into the supposed operations of 1901 their knowledge of spot welding which had been acquired in later years.

The Court will notice, when it reads the testimony of the defendant's witnesses, how unduly cognizant they are of the eighteen year old "facts" concerning which they had been coached and concerning which their recollection had been refreshed by McBerty's false story and misleading

catalogue, photographs and specimens, but how very inaccurate and deficient were their recollections about any other facts on which they had not been thus coached and refreshed. For example, Craft testified that he gave McBerty an affidavit in 1913, when it was in fact in 1917 (X-Q. 121, Vol. II, p. 782; X-Q. 261, p. 794), and he could not recollect "whether it was before or after the war" that he talked with Mr. Pattison (X-Q. 107, p. 781).

The fact of the matter is that the testimony of the witnesses other than McBerty is based merely on McBerty's story and on his worked up evidence and his misleading photographs and exhibits.

The substance of this McBerty prior use defense is now built on the supposed showing of the cut of the G-2 fan in the 1901 catalogue of the Warren Electric & Specialty Company first discovered in 1917.

With the sweeping away of this basis for the McBerty defense goes its entire substance.

PRIOR USE MUST BE PROVED BEYOND A REASONABLE DOUBT BY CONTEMPORANEOUS CONCRETE EVIDENCE.

The law of prior use and the attitude of the courts toward attempts to invalidate a meritorious patent by such testimony as is set before the court by the defendant in this case is presented completely and conclusively in the recent case of *Eibel Co.* v. *Paper Co.*, 261 U. S. 45, in which this Court rejected as "incredible" (p. 60) the testimony of alleged prior uses. This Court said (p. 60):—

> "It is true that some witnesses testify that they realized before Eibel's application that speeding up the stock to equal velocity with the wire would solve the difficulty and aid the speed. But there is not a single written record, letter or specification of prior date to Eibel's application that discloses any such discovery by anyone, or the use of the pitch of the

wire to aid the speed of the machine. The oral evidence on this point falls far short of being enough to overcome the presumption of novelty from the granting of the patent. The temptation to remember in such cases and the ease with which honest witnesses can convince themselves after many years of having had a conception at the basis of a valuable patent, are well known in this branch of law, and have properly led to a rule that evidence to prove prior discovery must be clear and satisfactory. *Barbed Wire Patent Case*, 143 U. S. 275, 284; *Loom Co.* v. *Higgins*, 105 U. S. 580, 591."

In the *Barbed Wire Case* there were a number of prior uses set up, the principal one of which was the exhibition of a panel of a barbed wire fence at a county fair by one Morley. Some twenty-four witnesses were produced on behalf of the defendant who testified to the existence of this fence. The court held that the prior use had not been sufficiently proved, saying:—

"We have now to deal with certain unpatented devices claimed to be complete anticipations of this patent, the existence and use of which are proved only by oral testimony. *In view of the unsatisfactory character of such testimony, arising from the forgetfulness, of witnesses, their liability to mistakes, their proneness to recollect things as the party calling them would have them recollect them, aside from the temptation to actual perjury, courts have not only imposed upon defendants the burden of proving such devices, but of declaring that the proof shall be clear, satisfactory and beyond a reasonable doubt. Witnesses whose memories are prodded by the eagerness of interested parties to elicit testimony favorable to themselves, are not usually to be depended upon for accurate information.* The very fact which

courts, as well as the public, have not failed to recognize that almost every important patent, from the cotton-gin of Whitney to the one under consideration, has been attacked by the testimony of witnesses who imagined they had made similar discoveries long before the patentee had claimed to have invented his device, has tended to throw a certain amount of discredit upon all that class of evidence, and to demand that it be subjected to the closest scrutiny. Indeed, the frequency with which testimony is tortured or fabricated outright to build up a defence of the prior use of the thing patented, goes far to justify the popular impression that the inventor may be treated as the lawful prey of the infringer. The doctrine was laid down by this Court in *Coffin* v. *Ogden* (18 Wall. 120), that 'the burden of proof rests upon him', — the defendant, — 'and every reasonable doubt should be resolved against him. If the thing were embryotic or inchoate; if it rested in speculation or experiment; if the process pursued for its development had failed to reach the point of consummation, it cannot avail to defeat a patent founded upon a discovery or invention which was completed, while in the other case there was only progress, however near that progress may have approximated to the end in view'. . . . Fourth: *If any experiments were made by Morley in this direction, they were evidently looked upon by him and by the public as of no practical value, and were subsequently abandoned and the fences lost.* . . . There was, evidently, prior to Glidden's application more or less experimenting in a rude way in and about Delaware County upon the subject of barbed wire as applied to wire fences. . . . *It is possible that some one of these experimenters may have, in crude way, hit upon the exact device patented by*

Glidden, although we are not satisfied from this testimony whether or by whom it was done."

"It is quite evident, too, that all, or nearly all, of these experiments were subsequently abandoned."

In *Deering* v. *Winona Harvester Company*, 155 U. S. 286, the testimony was that a certain pivoted extension for a grain binder, which was produced as an exhibit, was used to cut part of 250 acres and was subsequently abandoned for other reasons than any defect in the device. The use was testified to in considerable detail by the alleged prior user, and there were other witnesses. The court held that the proof was not sufficient, saying (p. 300):—

"As we have had occasion before to observe, *oral testimony, unsupported by patents or exhibits, tending to show prior use of a device regularly patented is, in the nature of the case, open to grave suspicion. The Barbed Wire Patent*, 143 U. S. 275. Granting the witnesses to be of the highest character, and never so conscientious in their desire to tell only the truth, the possibility of their being mistaken as to the exact device used, which, though bearing a general resemblance to the one patented, may differ from it in the very particular which makes it patentable, are such as to render oral testimony peculiarly untrustworthy; particularly so if the testimony be taken after the lapse of years from the time the alleged anticipating device was used. If there be added to this a personal bias, or an incentive to color the testimony in the interest of the party calling the witness, to say nothing of downright perjury, its value is, of course, still more seriously impaired. This case is an apt illustration of the wisdom of the rule requiring such anticipations to be proven by evidence so cogent as to leave no reasonable doubt in the mind of the court, that the transac-

> tion occurred substantially as stated. . . . If he ever used a pivoted device at all — of which we have considerable doubt — *his efforts in that direction must be relegated to the class of unsuccessful and abandoned experiments which, as we have repeatedly held, do not affect the validity of a subsequent patent. Corn Planter Patent*, 23 Wall. 181, 211. *Coffin* v. *Ogden*, 18 Wall. 120, 124."

In *Emerson & Norris Co.* v. *Simpson Bros. Corporation*, 202 Fed. Rep. 747 (C. C. A. 1st), the defendant sought to prove prior use by a number of very respectable witnesses whose evidence was supported by letters and a diary. The evidence was sufficiently strong to persuade the lower court that the prior use had been proved beyond a reasonable doubt. The upper court, however, considered that it was not sufficient, saying (p. 749):—

> "This case (*Brooks* v. *Sacks*, 81 Fed. 403), however, developed the underlying rule that ordinarily, in cases like the present, *it is necessary that the anticipations should be supported, not merely by the testimony of one or numerous witnesses relating to matters many years previous, but by concrete, visible, contemporaneous proofs which speak for themselves.* . . .
>
> "*The result of all these cases is that*, with reference to questions of the class which we have here, namely, the identity of structure as between what is patented and what is alleged to have anticipated it, *something more than oral testimony, even of the highest character, is required where there has been a considerable lapse of time.*"

The attitude of the courts towards such evidence as that of McBerty and his witnesses has been stated many times. In *Wood* v. *Cleveland Rolling Mill Company*, 4 Fish.

P. C. pp. 550, 559, the court (Swayne and Sherman, JJ.) says:—

> "The confidence of the attacking witnesses is often in proportion to the distance in time that one is removed from the other. Their imagination is wrought upon by influences to which their ears are subjected, and beguiles their memory."

This general proposition fits the facts of the case at bar.

In the recent case of *Nicholas Power Co.* v. *C. R. Baird Co.*, 222 Fed. Rep. 933, Judge Mayer states very well the test which should be applied to the McBerty defense:—

> "This case has given me some practical realization what a jury contends with when the court charges the doctrine of reasonable doubt in a criminal case, and after much consideration and a good deal of debate with myself I can only say that I am not convinced beyond a reasonable doubt. In other words, if, sitting as a juror, I were charged that, if I believed that it was proved beyond a reasonable doubt that Wooden had used the valve at the time in question, then he was guilty, I would bring in a verdict of not guilty; and if, *per contra*, I were similarly charged that, if Wooden had not used the valve at the time in question he was guilty, I should likewise bring in a verdict of not guilty — and both results would be because I entertained a reasonable doubt.
>
> "But there is something besides the question of reasonable doubt upon this branch of the case. I think that even if Wooden's recollection is right, the testimony shows that the valve and the machine with which it was made *were experimental and afterwards abandoned.* Wooden evidently had no appreciation of what the valve accomplished, and, instead of giving something to the world, he consigned the structure

literally to the junk heap, where doubtless it would have still remained, had this litigation not occurred.

"In what has been observed supra I am to be understood as not reflecting in the slightest upon the uprightness of Wooden. He looks and acts like an honest and truthful man, but experience in the court room teaches that honest men, after much thought and talk about just such an incident as this, sometimes become confused as to dates, and reiteration in conversations is often transmuted into a recollection honestly believed in, but inaccurate in point of fact."

In *Thayer* v. *Hart*, 20 Fed. 693, Coxe, J., said:—

"It is so easy to fabricate or color evidence of prior invention and so difficult to contradict it, that proof has been required which does not admit of reasonable doubt."

". . . The evidence of prior invention is usually entirely within the control of the party asserting it, and so wide is the opportunity for deception, artifice or mistake, that the authorities are almost unanimous in holding that it must be established by proof clear, positive and unequivocal; nothing must be left to speculation or conjecture."

EVEN IF McBERTY'S STORY WERE TO BE ACCEPTED AS TRUE IN TOTO, IT AMOUNTS ONLY TO AN ABANDONED EXPERIMENT, INSUFFICIENT TO ANTICIPATE A PATENT.

Having now established, as we believe, that McBerty's story is not and cannot be true, and that all McBerty ever did in 1901 (it is doubtful if he did even this) was at most to make a few unsuccessful experiments, resulting in only such abortive samples as the Lipps Exhibit H, we return to the proposition with which we began our discussion of this defense, namely, that even if the story is true in

substance and in detail, still the defense must fail for the reason that at best all that McBerty did amounted only to an abandoned experiment. The most that McBerty claims to have done was to make a trayful of spot welded fan spiders and blades—about a dozen. This work was done inside of a week, he says, and might have been done in an hour's time unless the machine overheated (Vol. II, p. 821, X-Q. 445; p. 822, X-Qs. 456–459). The experiment was admittedly abandoned and no more fans of the kind were ever manufactured after February, 1901. Thereafter the machine was used only for its regular intended purpose, butt welding the ends of guard rings.

Even defendant's own witnesses characterize the operations as purely experimental. Thus Craft testifies (Vol. II, p. 787):—

> "X-Q. 185. Do you regard this matter of welding blades to spiders by spot welds as experimenting or not?
>
> *A.* Yes, **most distinctly experimenting.**"

Similarly Lipps says that the fans alleged to have been spot welded "were not going through the commercial part of it", but the thing was **"just experimental"** (X-Qs. 83–85, Vol. II, p. 923). And Powers also says:—

> "All of the spot welding that I can recall was **experimental or development work.**" (Q. 35, Vol. II, p. 875.)

Similarly Brown in his affidavit, prepared by Mr. Howe in collaboration with McBerty himself, says:—

> "This spot welding was not done on any commercial product of the company, for as I understood it there was no commercial product of the company to which it was adapted as a commercial proposition." (Vol. I, p. 482.)

Indeed, McBerty in his letter to his own counsel, Mr. McGill, when he first presented the matter to him, classifies his work merely as "experimenting", saying:—

> "I have also samples of spot welding which was done on the welder at the time we did **this experimenting.**" (See his letter under date of January 2, 1912 [error for January 2, 1913], Vol. II, p. 945.)

This was written after Mr. McGill had expressly warned him in his letter of December 10, 1912 (Vol. II, p. 951), that "if the machine was constructed and used in an experimental way and then abandoned, it will not be available as a defense".

Indeed, *the affidavits and testimony of McBerty and his other witnesses are in considerable part devoted to showing why it was that the matter never got beyond the experimental stage and was abandoned instead of being adopted commercially.*

Under these circumstances, what McBerty did, even if we were to accept his whole story as true, falls clearly within the authorities which hold that abandoned experiments do not anticipate a patent. It was a mere experimental trial of the process and even if it happened that some few articles produced in the experimenting were sold, the use of the process was none the less mere experimentation, shortly abandoned. We cite a few of the many authorities on this point.

In *The Corn Planter Patent*, 23 Wall. 181, 211, a machine was used for planting five acres of corn, "but the machine was never used again, and was afterwards broken up and no other was ever made". The court held that there was no anticipation, on the ground that the alleged prior invention was a mere abandoned experiment.

In *Smith* v. *Goodyear Dental Vulcanite Co.*, 93 U. S. 486, 498, the Supreme Court held of certain experiments and

manufacture which closely resembled the patented process:—

> "The experiments resulted in nothing practical. . . . In consequence of these and other objections *the manufacture* was soon abandoned, and it may properly be considered an abandoned experiment."

In *Warren Bros. Co.* v. *City of Owosso*, 166 Fed. 309 (C. C. A. 6th), the suit was on the Warren bitulithic pavement patent, filed 1901 and granted 1903. The principal defense was a sidewalk laid by the Asphalt Street Paving Company (the real defendant) before its office in 1897. The court did not decide whether or not this sidewalk had the same structure as the patented pavement, simply stating (p. 315) that if defendant's evidence is to be believed it had the structure claimed in the Warren patent. The sidewalk was held not to anticipate since it was a mere experiment, saying (p. 315):—

> "That somebody had, in fact, made the same composition before he did does not necessarily defeat his patent. In one sense, he would not be the first inventor in such case. But, in the sense of the patent statute, he is the first inventor who by his own thought, makes an article or material and first perfects and adapts his discovery to actual use, *although someone may have previously made a similar article without putting it to practical use or giving his discovery to the public in any way.*". . .
>
> "The presumption is strong that the experiment was not regarded as successful in teaching anything of value to the pavement art, for it was never repeated, and no sidewalks were ever put down of that character, although that kind of work was a part of their business. It was an experiment when the pavement was laid, and continued to be such until the

> result could be proved. The subsequent continued use of their old sand and asphalt mixture, both for sidewalks and street purposes, for nearly six years and down to the infringement here complained of, is conduct plainly indicating that they had abandoned their efforts to find a better composition and treated the experiments of Upham in 1896 as unsuccessful."

In *Gamewell Fire-Alarm Telegraph Co.* v. *Municipal Signal Co.*, 61 Fed. 948, 952 (C. C. A. 1st Cir.), the court held that the Noyes patent was not anticipated by the Wood device, which had been embodied in a model and described in an application for a patent, saying:—

> "The only use ever made of it by Wood was merely experimental. It was never used for any practical purpose."

In *Hoyt* v. *Slocum*, 26 Fed. 329, 330, it was claimed that the prior use of two Harvey bottle-washing machines anticipated the patent in suit. One of these machines "was only used for a limited period by the person who invented it, and whose business made it necessary for him to wash bottles, and was then abandoned". The other machine was used "at times during several months", and was abandoned "principally because it ran so hard". Judge Colt held that there was no anticipation, saying:—

> "Both these Harvey machines were thrown aside after a short time, and they may fairly be considered as abandoned experiments; at least the priority of the Harvey machine has not been proved with the clearness and certainty which are necessary."

In *Mast, Foos & Co. et al.* v. *Iowa Windmill & Pump Co.*, 68 Fed. 213, 223, the patent was for a pump, and it was claimed to have been anticipated by a single pump that was actually made and used in a well years before the

invention was made by the patentee. The court (Shiras, J.) said:—

"It is well settled that to sustain the defense of prior invention or use, the evidence must be clear, satisfactory, and such as to leave no reasonable doubt as to the material facts. Furthermore, when it appears that several parties have been independently engaged in experiments upon the same invention or device, the one who succeeds in first giving it a practical form, who brings it to public knowledge by obtaining a patent therefor, and makes it of general use and value by manufacturing and causing to be manufactured machines or articles embracing the invention, will be protected in the rights secured by his patent, even though it be shown that another may have mentally conceived the invention at an earlier day, *or even if, in addition to the mental conception, he may have embodied it in a successful experimental form and then abandoned it. The benefits and protection of the patent law are not for those who indulge in speculations and experiments only*, but are intended to protect those who make available to the public novel and useful inventions by following up the original conception, carrying it through the experimental stage, and so far perfecting it as to furnish to the public a practical means of utilizing the novelty sought to be patented. *Barbed Wire Patent*, 143 U. S. 275, 292, 12 Sup. Ct. 443, 450; *Coffin* v. *Ogden*, 18 Wall. 120; *Cantrell* v. *Wallick*, 117 U. S. 689, 6 Sup. Ct. 970; *Deering* v. *Harvester Works*, 155 U. S. 287 15 Sup. Ct. 118. It may, therefore, be admitted that the evidence shows that Johnson was experimenting in the same direction pursued by Martin, and that his efforts in this line antedated those of Martin; but it is no less clear that if the public knew no more of the

invention than was communicated to it by the making and use of the Felger pumps, in 1883 and 1884, it would be in entire ignorance of the improvement. *The experiment was made and then abandoned; that is to say, it was not made the basis of an application for a patent, nor was the manufacture and sale of pumps embracing the invention entered upon.* I do not, therefore, deem it necessary to consider in detail the evidence upon the question of the actual date of the making of the Felger pumps, as it must be held that they do not defeat the Martin patent, even if made before the date thereof."

In *Standard Sanitary Mfg. Co.* v. *J. L. Mott Iron Works*, 152 Fed. 635 (affirmed 129 Fed. 135, C. C. A. 3d Cir.), Judge Cross said (p. 638):—

"The defendant, however, alleges that the patent is invalid because of the prior use of an unpatented pneumatic device of a like character to accomplish the same purpose. In support of this contention considerable evidence has been produced, from which it appears that a few bath tubs were enameled with some degree of success by the defendant in the fall of 1896 by a device in some respects similar to that defined in the complainant's patent; but I think that the evidence, considered as a whole, discloses nothing more than an abandoned experiment. The device — there was but one — was in operation, so that workmen who used it say, off and on for about a week or ten days, although one or two other witnesses intimate that it was used for a somewhat larger period. It was then unquestionably dismantled, and was not again used; nor was anything like it used for several years afterwards, and not until after the defendant had removed its works from Mott Haven, N. Y., to

Trenton, N. J. . . . It certainly was used but a very short time, and was then abandoned."

The defense was therefore held insufficient.

SUMMARY AS TO McBERTY DEFENSE.

McBerty had a butt welding machine in 1901 and on it he possibly may have done some unsuccessful and fruitless experimenting, resulting in such abortive products as the Lipps Exhibit H, which fell very far short of any tangible or usable result. We deny that even this much is proved.

In 1913, confronted by a charge of infringement of the Harmatta patent, McBerty seized upon his 1901 abandoned experiments as a club with which to force a "settlement" with the Thomson Company. He, therefore, worked up affidavits in conjunction with his counsel, Mr. McGill, approached the Thomson Company with them, and made a proposition to sell his evidence to them for suppression.

Honest men do not make such propositions.

When this proposition was rejected, McBerty communicated his story to the counsel who were defending the Barney & Berry case and spent weeks of his time aiding them in collecting evidence and affidavits, giving them every possible assistance in the effort to build up a successful defense. When these affidavits were all collected and considered, McBerty's story was rejected by these counsel — among the most capable, successful and reputable firms at the bar — as being not true, and if true, as only amounting to the attempted resurrection of an abandoned experiment.

McBerty then took a license under the Harmatta patent for his company, in which the validity of the patent was recognized.

Then in 1917 the "Welding Patents' Investigating Com-

mittee" appeared on the scene, saw McBerty and in co-operation with him took steps to revive the discredited defense.

His growing legal experience had now taught McBerty that his story as previously told had at least two fatal defects — (1) lack of commercial use of the process — and (2) lack of record date evidence. So, now, the story experienced a prodigious growth.

The cut of the G-2 fan in the Warren Company's 1901 catalogue was found and seized upon as plausible "record evidence" in support of a proposition never before advanced or hinted at by McBerty to his own counsel or to the counsel for the Barney & Berry Company, namely that a dozen or fifteen fans with spot welded spiders and blades had gone into the commercial output of the Warren Company. This catalogue cut is really the whole basis upon which this "trayful of fans" addition has been built.

But it is now shown by defendant's own witnesses that the catalogue was published months before February, 1901, when McBerty claims to have done this spot welding, and even months before the butt welding machine on which he claims to have done the work was set up. Moreover the cut shows not a rivetless, but a riveted fan.

Further to support the story, McBerty now (in 1917) reconstructed his old 1901 spot welder, parts of which he had found in the junk room of the Peerless Company, and remounted it in such a manner that fan blades and sheet steel spiders could be inserted within it — which had been impossible as it was mounted in 1901 — and put on a new transformer capable of giving sufficient current for spot welding, which the 1901 transformer could not do — and proceeded to make some samples of spot welded work on this reorganized machine.

Forthwith there appeared at the same time, 1917, something which had been utterly lacking at the time

when the facts were so fully investigated in 1913 by McBerty's counsel and by Mr. Howe, namely a dated specimen, — McBerty's Exhibit M, — which is clearly shown, we submit, to be spurious.

This misleading catalogue cut, this remodelled machine and these recent specimens of spot welded work were diligently shown by McBerty and the defendant's witness and paid agent, Smith, to many persons who in 1913 when interviewed by Howe and McBerty had failed to remember any spot welding, and by this means and by dint of persistent coaching, some few of these persons were induced to come forward with testimony wholly inconsistent with their 1913 affidavits and to say what they may or may not have come now to believe, that they remember seeing spot welded fan blades in the year 1901. But no one of them goes so far as to say that he ever actually saw McBerty or anyone else doing the work of spot welding the dozen or fifteen fan blades and spiders which McBerty tells about; and many witnesses who were in a position to know what was done on the 1901 machine could not be so persuaded; they testify that they never knew of this machine being used for any purposes other than butt welding.

No fan with spot welded blades is produced, and absolutely the only alleged contemporaneous specimen of the McBerty work testified to by any other witness than McBerty himself is the Lipps Exhibit H, which is not spot welded at all, but a mere unsuccessful "stick". This exhibit, put in evidence not by defendant but by plaintiff, by itself, if valid, alone goes a long way to prove that McBerty never did any real spot welding in 1901, for naturally Lipps would have preserved as good a sample as he could have found of McBerty's work.

There is then no record evidence whatever, "no contemporaneous concrete evidence that speaks for itself" of any kind, but only the discredited word of McBerty him-

self, and the inconclusive and contradictory oral evidence, eighteen years after the event, of a few witnesses coached by spurious and misleading exhibits and contradicted by their own 1913 statements.

But the story cannot be true. It breaks down when its details are analyzed. As we have shown there are at least three positive reasons why McBerty cannot have done what he claims to have done in 1901; namely (1) that the machine as it was in 1901 had not sufficient space to accommodate fan blades and spiders; (2) that it had not a transformer capable of supplying adequate current for spot welding and (3) that the spiders used on the G-type fans were not steel but brass.

The McBerty story does not fail merely for lack of proof but because it is positively disproved.

And, finally, if it were all true throughout, trayful of fans addition and all, it would still be no defense, because, even so, it would clearly fall within the category of abandoned experiments which do not militate against the validity of an issued patent.

EVENTS OCCURRING AFTER DECEMBER 3, 1903, CANNOT AFFECT THE VALIDITY OF HARMATTA'S PATENT.

The application for the Harmatta patent in suit was filed December 3, 1903, at which time Harmatta's rights to his invention became fixed and nothing occurring thereafter can affect the novelty or standing of that invention in the art.

Consequently the proofs offered by the defendant as to any spot welding done subsequent to December 3, 1903, are immaterial to the issues of this case, which relate only to the novelty and patentability of Harmatta's invention at that date.

It is immaterial that William E. Smith in 1905 may have

built a welding machine (long since scrapped) for butt welding at the works of the Carnegie Company, however much that machine might have resembled the McBerty welder (Smith, Q. 133, Vol. I, p. 504; McElray, Vol. II, p. 910), and it is likewise immaterial if at some later date the machine was altered over to do spot welding (McElray, Q. 21, p. 911).

It is also immaterial if Taylor, another of defendant's witnesses, made a roller welder for the Winfield Company in 1904 (Q. 56, Vol. II, p. 897), which he later used for spot welding (Q. 45), or if the Winfield Company later built a butt welder (Q. 64) and later a spot welder (Q. 68). Taylor's testimony, taken at its face value, simply shows that he invented spot welding at a later date than Harmatta. Taylor's statement that in 1903 he saw spot-welding at the factory of the Peerless Company, the successor of the Warren Company (Q. 16, Vol. II, p. 893), is not to be credited, for both McBerty and Smith admitted and indeed stated most emphatically that no spot welding was done at that factory after the year 1901 (Vol. II, pp. 830, 831, and Vol. I, p. 520).

Whether spot welding was first developed in the United States from knowledge derived from Harmatta or from knowledge derived from some later inventor is not of prime importance. Harmatta's rights were fixed by the filing of his application December 3, 1903.

The fact is, however, that spot welding was first introduced commercially into the United States directly through Harmatta and the Eisenhutte Silesia Company, the owner of Harmatta's rights, at the works of the National Enameling & Stamping Company of Baltimore, Md., in 1904 (*supra*, page 14). Since then the National Company has built and used between eighty and one hundred spot welding machines (Herring, Q. 18, Vol. I, p. 132). The enormous amount of kitchen-ware made by

that company in which the sheet metal parts were united by Harmatta's spot welding of course carried the knowledge of this new art all over the United States.

With this extensive commercial use of spot welding in the United States, directly developed from Harmatta's invention, so fully proved, any basis for any argument that the defendant may make to the effect that the commercial use of spot welding did not originate with Harmatta, is entirely swept away.

It was not until two or three years later, that is in 1906 or 1907, that the Winfield Company, confessedly the first outside of the National Enameling & Stamping Company to practice spot welding commercially, started to put spot welders on the market (Taylor, Q. 73, Vol. II, p. 898). The first of these was sold in 1908.

All these occurrences took place long after the date of the filing of Harmatta's application and are really of no direct importance in determining the standing of Harmatta's invention in this case, and would not be discussed but for defendant's arguments about them.

CHAPTER IV.

THE RELATIONS OF THE PLAINTIFF TO RIETZEL AND TO THE RIETZEL PATENT.

The application for the Harmatta patent in suit was filed December 3, 1903. This is the Harmatta date of invention for the purposes of the case. From and after that date he had an absolute right to patent the invention disclosed in that application if it were found to be new and patentable. This he did in the patent in suit.

In prosecuting the application he complied with all the provisions of law and is in no way responsible if because of the cumbersome character of Patent Office proceedings, the record was to some extent confused or the issue of his patent was delayed.*

The Rietzel patent No. 928,701 (Vol. II, p. 1098), was applied for February 24, 1905, and issued July 20, 1909. Of course, this patent is too late to affect Harmatta's rights.

It was open to the defendant to show that Rietzel was the prior inventor. It called Rietzel as a witness. We have already shown (*supra*, p. 69) the utterly frivolous character of the definitely abandoned experiments to which Rietzel testifies as having been made by him in 1898, five years before the date of Harmatta's application and seven years before Rietzel's application for his patent. Rietzel was certainly not the prior inventor.

We submit that this is all there is to any defense based upon Rietzel or his relations to the general situation.

But the defendant in the Court below sought to develop

*We call attention to the law on this point as stated in the case of *U. S.* v. *American Bell Telephone Co.*, 167 U. S. 224, 248.

from the relations of the parties a defense which it seems to present as in the nature of an estoppel, not affecting in the slightest degree the facts in the case or Harmatta's clear right to the patent as far as Rietzel or his work is is concerned.

Defendant's argument seems to be that because there appeared in the Rietzel patent of 1909 certain claims which *at the suggestion of the Patent Office* were incorporated into the Harmatta application in the year 1910, which claims clearly and definitely define Harmatta's invention and as such were allowed and appear in the Harmatta patent in suit, and because Rietzel filed certain affidavits in the course of his application and certain preliminary statements in an interference with Harmatta's application which contained some general statements which Rietzel, when called as a witness, failed adequately to support, and because the plaintiff's predecessor was the owner of the Rietzel application and patent and subsequently purchased the Harmatta application in the year 1912, in some way the plaintiff is estopped from holding the defendant for its clear infringement of the Harmatta patent.

Regardless of any other consideration, it seems certain that there is no element of estoppel in the situation. Neither the plaintiff's predecessor nor Rietzel has done or said anything upon which the defendant might properly rely as justifying it in its infringement of the patent in suit. Nothing that they or either of them said or did was in fact relied upon by the plaintiff in initiating and carrying on its infringement. No injury to the defendant because of anything said or done by Rietzel or the Thomson Company is even alleged. The defendant relies only upon the fact that Rietzel during the progress of his application and in his preliminary statements made certain allegations which upon investigation he was unable to prove and upon the confusion that arose from a very difficult situation in which the old Thomson Company found

itself involved when it learned of the Harmatta invention and that it was Harmatta and not Rietzel who was entitled to certain claims in the Rietzel patent which was at that time owned by the Thomson Company. A brief statement of the history of the two applications and of the way in which the rights of the matter were worked out by the Thomson Company and the Patent Office will show how utterly without foundation is this contention of the plaintiff.

In the year 1904 Rietzel developed the specific projection welding process which he disclosed in his patent (Vol. I, p. 659, XQ. 162). This was his first real work and the earliest date upon which he can stand for any invention patented in his patent No. 928,701, for his abandoned experiments seven years before are clearly to be ignored. The welding invention which Rietzel made in 1904 was in no sense the Harmatta invention. He was, to be sure, seeking to unite by electric welding two sheets of metal, a thing which had not been done before by anyone except Harmatta, whose invention had been completed by the filing of his application December 3, 1903, but Rietzel's method was utterly unlike that of Harmatta. It is well disclosed in the Rietzel patent.

Rietzel's thought was to unite two sheets by the following method: First, as a preliminary step, he made a series of projections on one or both sheets by bending up the metal as shown in Figs. 1 and 2 of his patent or by putting metal points or projections on the face of one or both sheets as shown in Figs. 3 and 4 of his patent, or by introducing a series of metal pieces between the sheets as shown in Fig. 5 of his patent which acted like points or projections. These points or projections were to obtain "the localization of the flow of heating electric current and of welding pressure to the desired spot or spots" (Rietzel Patent, p. 1, lines 93-96).

His preferable method was "to provide projections from the meeting surfaces of both pieces that are to be united" (Patent, p. 2, lines 22–25), although his idea would be practised if he had projections on only one sheet or even if he interposed between the two plane sheets "small pieces of conducting material" which act in the same manner as projections for localizing the heating current and the pressure (Patent, p. 2, lines 26–31).

His electrodes, utterly unlike the tapered electrodes of Harmatta, the end of each of which is of the size of the spot to be welded, are shown at A, A′ in each of the first five figures of the Rietzel patent and described as "conducting blocks" covering the *entire series* of spots to be welded. "These electrodes, A, A′, furnish the heating current while applying the pressure, the localization of the pressure in the spots being brought about" by the points or projections or inserted pieces of conducting material (Patent, p. 2, lines 98–107).

When the current is applied it passes through these large "conducting blocks" or electrodes (from one to the other) when "the application of pressure together with the flow of heating current from one plate to the other will result in a union of the two pieces over their opposed surfaces in spots only thereon" (Patent, p. 2, lines 119–124).

It is worth while to quote two passages from the Rietzel patent. The first is page 1, line 92, to page 2, line 40, which is as follows:

> "In carrying out my invention the localization of the flow of heating electric current and of welding pressure to the desired spot or spots may be brought about in any desired way. One of the preferred ways is by providing between the meeting surfaces or portions of the pieces to be united suitable conducting projections or points at the spots of union, which projections or points carrying the heating electric

current from one piece to the other are so located in the meeting surfaces and are separated from one another that on the application of the welding pressure the welded union resulting will be localized in the area of the opposed surfaces and will be substantially coextensive in area with the restricted area of the path of the effective heating current. Various ways of providing such points or projections will occur to those skilled in the art.

"The preferred method is to indent the metal from the side reverse to that on which the union is effected by a suitable tool, the projections thus formed affording points for the passage of the electric current. This method is preferable also because it permits the welding to be produced at a multiplicity of spots simultaneously through the application of pressure over the whole rear surface of the plate, the points or projections in that case serving not only to localize the flow of the heating current but also to localize the welding pressure.

"In the preferred manner of carrying out my invention in the case of sheet metal manufacture I provide projections from the meeting surfaces of both pieces that are to be united. Said projections may also be provided by interposing between the two plane sheets small pieces of conducting material which act in the same manner when the sheets are brought together, as projections which localize the heating current and the pressure. It will be understood, however, that in the latter instance as in the former, these pieces are so small and are placed such a distance apart that on the application of welding pressure there will be no running of the welds into one another but that the final union will be in spots only leaving well-defined areas on the meeting surfaces, in

which the surfaces either lie in contact or separated from one another by a very thin space."

The second is at page 3, lines 23 to 30, as follows:

"When the invention is employed in its preferred form or manner of practice in the field of sheet metal manufacture all that is necessary is to provide the contact spots or projections as already described and then to assemble the pieces in an electric welding machine and weld them together as already set forth."

As already stated, this Rietzel process is one of "butt welding". It may be described in the exact terms that would be used in describing the Thomson butt welding operation of his fundamental patents. It is utterly different at every stage from the process patented by Harmatta. In Rietzel, when the plates are put together at the beginning of the operation, they are not in contact except at the points or projections (the inserted piece of metal of Fig. 5 is in all respects the same as a projection). In Harmatta the current and pressure are localized solely by the electrodes which are pointed, the point being of the size and dimensions of the spot to be welded. In Rietzel the electrodes are "conducting blocks" which cover a substantial area of the plates within which are a series of points or projections.

But the result of the Rietzel process would be sheets welded at spots, of which Harmatta and not Rietzel was clearly the first inventor. In so far as the process was one of welding in spots, the points or projections on the plates of Rietzel were of vital consequence, as with his process the welded spots were obtained by butt welding these spots or projections. Harmatta has no points or projections but, as we have shown, works upon an utterly different principle.

It is obvious, however, that as a matter of words, phrases may be found which would apply to both processes but having a different meaning as to each. But Harmatta invented his process long before Rietzel invented his so that Harmatta was entitled not only to the claims for the product but also to any claims so vaguely drawn as to define both processes.

While Rietzel's app'ication for point and projection welding was pending, the Patent Office on the eighth day of June, 1908 (Vol. III, p. 1760), called attention to the British patent to Harmatta No. 22,981 of 1903 accepted August 25, 1904, its effective date. This patent (Vol. II, p. 1123) describes among other things the precise electrode spot-welding process of the United States Harmatta patent in suit. It states (p. 1128): —

> "If now, for example, two overlapping sheet metal ends to be welded be introduced between the electrodes *a*, *b*, and the latter pressed towards one another and current allowed to flow, then a small round and clean welding point is obtained which fully takes the place of a rivet."

The Patent Office said (Vol. III, p. 1760):—

> "Fig. 4 of this [the British] patent shows a spot weld, which takes the place of a rivet."

Thereupon Rietzel's so'icitors, properly anxious to get as broad claims as possible for their client, redrafted Rietzel's specification and claims to cover broadly the idea of making a weld which would take the p'ace of a rivet between two sheets of metal by localizing the current and the pressure at the spot to be welded, however it was done. (Vol. III, pp. 1762-1775).

Their theory undoubtedly was that the finished spot welds produced by the two processes were practically the

same and that claims might be drawn on Rietzel's utterly different process which would cover the Harmatta process.

In making these substantial amendments to the Rietzel application, Rietzel's solicitors clearly had in mind the fact that Rietzel had actually reduced his projection welding invention to practice in June 1904, for they filed simultaneously an affidavit for Rietzel to that effect (Vol. III, p. 1778). This date, of course, was prior to August 25, 1904, the effective date of the Harmatta British patent, the only Harmatta patent to which their attention had been called.

The Patent Office then cited the French patents to Egel (Egel was patenting the Harmatta invention; under French law the inventor himself need not file the application) No. 336,187 and 335,889 (Vol. III, p. 1788). No. 336,187 (Vol. II, p. 1144) is substantially the same as the original specification of the application for Harmatta's United States patent. It was published March 1, 1904. No. 335,889 was published February 18, 1904 (Vol. II, p. 1132). These dates were back of June, 1904.

Thereupon Rietzel's solicitors, undoubtedly informed by Rietzel that he had done something on the line of his invention at an earlier date, filed an affidavit that he had made spot welds by the use of a "pointed electrode" before "*February 18, 1904*", the date of the French patent No. 335,889 (Vol. III, p. 1792).

Both these affidavits were the customary and usual affidavits provided for by Rule 75 of the Patent Office.

It may well be contended that Rietzel's solicitors should have investigated Rietzel's story at this time. If they had done so they would have found that his futile and fruitless abandoned work prior to February 18, 1904, which amounted only to an abandoned experiment, was not adequate to carry back his date. But Rietzel's memory of what he had done in 1898, so many years before the

affidavits were filed in the year 1909, may easily have deceived him into the belief that he had then done something material, although when he came to investigate the subject later, he found that such was not the case.

In any event we respectfully submit that there is nothing in the situation to cast the slightest cloud on the Harmatta patent or the plaintiff's right to enforce the same.

The Rietzel patent finally issued July 20, 1909.

The patent was clearly invalid in view of Harmatta's earlier invention both as to the claims of the product and also as to the broad claims inserted by Rietzel in his application in view of Harmatta, if the same should be construed, as they might be according to their terms, as covering more than the production of projection or point welding which alone Rietzel had invented, for Harmatta had a fixed and certain date for his invention of electrode spot welding, namely December 3, 1903, when he filed his application.

It is to be observed that Rietzel's affidavits which only undertook to carry his date of invention back of February 18, 1904, did not purport to carry it back to December 3, 1903, which is Harmatta's date.

It is respectfully submitted that the whole matter is utterly immaterial and that the Court will be only interested in the determination of whether Rietzel anticipated Harmatta in the invention of the subject matter of the patent in suit. It is perfectly clear that he was not such prior inventor.

The Patent Office was clearly in fault in not calling Rietzel's attention to the Harmatta application for the patent in suit, which had been on file in the Patent Office since December 3, 1903; but the Rietzel patent issued July 20, 1909, without Rietzel or the old Thomson Company, which owned the patent, having any knowledge of Harmatta's application.

Rule 96 of the United States Patent Office provides: —

"96. Whenever the claims of two or more applications differ in phraseology but relate to substantially the same patentable subject-matter, the examiner, when one of the applications is ready for allowance, shall suggest to the parties such claims as are necessary to cover the common invention in substantially the same language."

If, therefore, the Patent Office had had the Harmatta application in mind and had regarded the application of Rietzel as relating substantially to the same patentable subject-matter as that of Harmatta or as having a "common invention", it should have suggested to Harmatta the broad claims of Rietzel and given Harmatta a chance to go into interference with Rietzel before his patent issued.

It seems probable that the Patent Office so thoroughly realized the difference between Rietzel's point and projection welding and the electrode spot welding of Harmatta that it did not occur to it that there could be a "common invention" involved. Even as to the product claims, the Office very likely construed them, carelessly as we think, as limited to the product of Rietzel's process, as they undoubtedly construed his broad process claims as limited to the point and projection and "conducting block" electrode features that were essential to them.

After the issue of the Rietzel patent, the Patent Office did in fact on March 22, 1910, suggest to Harmatta that he was entitled to make Rietzel's broad claims with which alone we are concerned in this branch of the case, thus giving to Harmatta the opportunity of inserting those claims in his application and of going into interference with Rietzel as to those claims.

Meantime, from December 3, 1903, to the date of issue of the Rietzel patent, Harmatta had been pressing his

application, persistently seeking claims for the "electrode process of electric spot welding" which he had fully disclosed in his original application and which Rietzel had never disclosed. But it was only on the suggestion of the Patent Office, calling his attention to Rietzel's claims, that he seems to have realized that upon his application might be based claims for a broad expression of the underlying idea of uniting sheets in spots by a weld to take the place of a rivet *whether the process was the "projection welding of Rietzel" or his own "electrode welding"*. He therefore took advantage of the opportunity offered by the Patent Office to ask for such claims (Vol. II, pp. 1419-1427).

It is immaterial for the purposes of this case whether those broad process claims when added to the Harmatta application (they appear in his patent as Nos. 1–6) do or do not cover more than the Harmatta electrode process of spot welding. For the purposes of this case the plaintiff would be quite satisfied with a construction of them which limits them to the electrode process so clearly defined by Harmatta. As to the product claims, Nos. 17–21 of the Harmatta issued patent, which were inserted at almost the same time, Harmatta was clearly the first inventor of the subject-matter of those claims whether made by his own process or that of Rietzel.

When an interference was declared April 14, 1910 (Vol. III, p. 1838), Rietzel and the old Thomson Company, the owner of his patent, knew for the first time of the Harmatta application.

They must have been greatly disturbed when this was brought to their attention, for here was an application filed December 3, 1903; with broad claims introduced at the suggestion of the Patent Office which might, if a patent should issue to Harmatta with those claims, cover the Rietzel process and product as well as the entire art of spot welding. They took exactly the course that is

always taken under such circumstances. First by motions to dissolve the interference (Vol. III, pp. 1852, 1920–1923) they endeavored to persuade the Patent Office that Harmatta was not entitled to make such broad claims. Failing in this effort, they were face to face with an interference in which was to be tried out the issue of priority of invention. The first step in the procedure had been the filing of preliminary statements. Harmatta stood on the date of his application December 3, 1903. In Rietzel's preliminary statements, he made the allegation that he had conceived the broad invention of his claims late in the year 1897 and that he reduced the invention to practice in the latter part of July, 1898, and at that time first explained it to others (Vol. III, pp. 1843, 1917). Two preliminary statements were filed because after the interference was first declared on certain claims, other claims were added, as to which a second preliminary statement had to be filed.

Thus Rietzel went back in his preliminary statements to his inconclusive, fruitless and abandoned experiments which are described in this record (Vol. I, p. 633, *supra*, p. 69) and if he had all the facts clearly in mind, it may well be contended that he was not justified in making such an allegation. It is reasonable to suppose, however, that when he made the preliminary statements, twelve years after his experimental work, he believed that he could show that he had done much more in 1897 and 1898 than he subsequently found himself able to prove when the situation was really investigated as preliminary to the taking of proofs.

He should perhaps have been more careful in his pleading, but the published opinions of the Patent Office tribunals and reported dicisions in patent cases as well as in interferences, show that it is but human and natural for inventors at the preliminary stages of a controversy

as to prior invention, and sometimes through to final hearing, to rely upon work which upon full investigation proves to be inadequate.

Such was the case here. Upon investigation counsel for the Thomson Company discovered that Rietzel could not carry his date of invention back of Harmatta's application of December 3, 1903, for his work of 1897 and 1898, which was all the work done by him prior to 1904, was merely futile and fruitless experiments which were utterly without significance. Also they were clearly abandoned for Rietzel did nothing after 1898 until the middle of the year 1904 after Harmatta's application had been filed (Townsend, Vol. I, p. 214, Q. 3).

We have (*supra*, p. 208) quoted decisions establishing the law on this point. We add here a few decisions of the Court of Appeals of the District of Columbia in interference cases to the same effect: —

Mason v. *Hepburn*, 1898 C. D. 510.
Warner v. *Smith*, 1898 C. D. 517.
Thompson v. *Weston*, 1902 C. D. 521.
Matthes v. *Burt*, 1905 C. D. 574.

The law is definitely settled.

The only course that seemed open to the old Thomson Company, to protect itself and its licensees and to save its commercial situation from ruin, was to buy the Harmatta application. It therefore sent Mr. Tischner abroad to see Harmatta and the Eisenhutte Silesia Aktien-Gesellschaft, which controlled his application. Tischner's mission was successful (Vol. I, p. 215). Harmatta executed an assignment of his application to the Thomson Company, February 3, 1912, which was given to the Silesia Company to be delivered to the Thomson Company when the agreement between those companies was "formulated and executed". This agreement (Vol. I, p. 429) was

delivered April 3, 1912, and with it the assignment, which was immediately recorded in the Patent Office, April 5, 1912 (Vol. III, p. 1948).

A very common situation was thus created where the rights of two interfering parties are owned by the same interest, in this case the Thomson Company. The Patent Office had been frankly informed of the situation by the recording of Harmatta's assignment. The Thomson Company had a choice of two courses of action. It could hire attorneys on each side to fight the interference through, take testimony on both sides, and carry the case to final decision through all the tribunals of the Patent Office and to the Court of Appeals for the District of Columbia, all of which would have involved a delay of years in the issue of the Harmatta patent; or it could investigate the facts, decide which of the two inventors was prior to the other, and stand on the patent to that inventor, thereby saving delay, litigation, expense and trouble and a prolongation of the patent monopoly.

The Thomson Company chose the latter course, which is a usual and clearly proper course under such circumstances and one which has been approved by the Patent Office and by the courts (*infra*, p. 233).

To bring this result about, the usual formalities were followed, Rietzel took no testimony, and on motion of Harmatta's attorney of record the issue of priority was decided July 22, 1912, in favor of Harmatta.

The Patent Office then further considered Harmatta's application, October 17, 1912, and cited a number of prior patents (Vol. II, p. 1434).

The attorneys for the Thomson Company, who had been substituted for Harmatta's former attorneys, amended the application, October 26, 1912 (p. 1436), nine days after the action of the Patent Office. This amendment brought the specification and claims to their present form.

The Patent Office allowed the application, October 31, 1912. The final fee was paid November 4, 1912 (p. 1455). The patent issued December 3, 1912. In all *only eight months* elapsed from the time the Thomson Company obtained title to the application to the time when it was issued. This is a record of extraordinary expedition.

The propriety of settling such a controversy as the Harmatta-Rietzel interference in this manner has been recognized by the courts.

In General Electric Company v. *Laco-Philips Company*, 233 Fed. Rep. 96 (S. D. N. Y.), the General Electric Company had acquired three pending applications for the Tungsten lamp which were in interference. The General Electric Company, instead of fighting the interference through, investigated and determined which application should prevail and had the patent issued on that application. This course of procedure was approved by the court (p. 100), which says:—

> "The situation was that the plaintiff had paid large sums of money for these applications and naturally was interested in securing a valid patent. It was, of course, a matter of indifference to plaintiff which application was successful, provided that the patent was rightly issued to the first and real inventor. Thus a heavy responsibility was laid upon the attorneys for plaintiff, and, as a result, a thorough investigation was made by them, and after cautious and thoughtful consideration, plaintiff was advised that the patent should issue in favor of the Just & Hanaman application. The fact that the plaintiff, under the advice of careful and experienced counsel, thus decided for itself upon which patent to stand, is evidence of an open and frank manner of dealing with a difficult problem, and ipso facto relieved the proceeding of

any suggestion of collusion, which might have followed had different counsel been engaged by plaintiff to urge the merits of the respective applications then pending."

The decision of Judge Mayer in the District Court was affirmed by the Court of Appeals, which adopted Judge Mayer's decision as its own (p. 107).

It seems clear that there is nothing in this story which affects the validity of the Harmatta patent or the right of the plaintiff to enforce it. The preliminary statements of Rietzel like his affidavit above referred to, even if they be criticised as careless — and we do not believe that they are a fair subject for condemnation — can not affect the rights of the parties in this controversy. There is certainly no element of estoppel. If Rietzel made a mistake, it was a natural mistake of fact, or rather of mixed fact and law, for which he is to be condemned, if at all, only for exaggerating what he had done, and for not at the time fully investigating the subject. His statements deceived no one and no one acted upon those statements to his own detriment. The defendant certainly has not been harmed in the slightest degree, neither has the public. A patent for the electrode spot welding invention has been issued to Harmatta, who was certainly the first inventor both of the process and the product. He was clearly entitled to that patent. The grant of just this patent to him is exactly what the patent law contemplated. There is clearly no element of estoppel which affects the situation.

Blemishes in procedure and careless misstatements and exaggerations are frequently made as part of the complicated procedure in the Patent Office. We call attention to a few authorities showing how the courts deal with

such errors although we respectfully submit that in this case there is no occasion for any appeal to authority.

In *Commercial Mfg. Co.* v. *Fairbank Canning Co.*, 27 Fed. Rep. 78 (N. D. Ill., Blodgett, J.), the patentee had stated in his application for a patent that the invention was the same as that for which he had taken out certain foreign patents. This statement was made in an affidavit. On suit on his United States patent, the defendant set up that the United States patent had expired with these prior foreign patents, the invention being the same, and the defendant urged that the plaintiff was estopped from denying the identity of the inventions in the American and foreign patents by reason of the statement made and filed in his affidavit in the Patent Office. The court held that the plaintiff was not estopped to deny that the same invention was involved in the American and foreign patents, saying (p. 81):—

> "We think there can be no doubt from the proofs in the case that both Medge and his solicitors, who are men of high standing in their professions, thought at the time the original patent was applied for that they were covering the substantial process which Medge had patented abroad; but if these parties were laboring under a mistake, their rights ought not to be defeated or seriously abridged by such mistakes, and we therefore feel compelled to examine the proof as to the identity of the foreign and American patents."

The decision of Judge Story in *Barrett et al.* v. *Hall*, 1 Mason, 447, is to the same effect. This was a suit on a joint patent where each of the joint patentees had previously obtained separate patents for the same invention and afterwards they had obtained the joint patent in suit. The lower court charged the jury that the existence of the two prior sole patents for the same invention granted to

the same patentees did not affect the validity of the joint patent declared upon. He also directed them that the oaths of the plaintiffs respectively, made when they obtained the said prior sole patents that they severally believed themselves to be the true inventors of said machine, did not preclude them from showing a joint invention of the same machine and to claim as joint patentees therefor. On appeal Judge Story held that this charge to the jury was correct, saying (p. 474):—

> "In the next place, if several patents are taken out by several patentees for a several invention, and the same patentees afterwards take out a joint patent for the same as a joint invention, the parties are not absolutely estopped by the former patents from asserting the invention to be joint; but the former patents are very strong evidence against the joint invention. The reason of this doctrine is, not that estoppels are odious in the law, but that a party may innocently mistake, as to the extent of his own claims; and though a sole and joint invention, by the same persons of the same thing, cannot exist in fact, yet a party may suppose, that he has invented, what in truth has been partly suggested by another mind."

In *Kohler* v. *Kohler & Chambers*, 47 O. G. 247; 1888 C. D. 19 (decision of Commissioner Hall), Kohler and Chambers filed a joint application, and subsequently Kohler filed a sole application for the same invention. The two applications had been assigned to different parties, and an interference having been declared the assignees of the joint application, which had issued into a patent, moved to dissolve the interference on the ground that no patent could issue to Kohler as sole applicant under these circumstances. The motion was overruled, the Commissioner saying that the interference would develop the

truth as to whether the invention was joint or sole, and that the applicant Kohler was not estopped by reason of his oath, filed with the joint application, from asserting his rights as sole inventor and that he should not be

> "denied a patent on account of having made an error or mistake as to the matter of his joint inventorship."

This situation has frequently arisen in the Patent Office, which has uniformly followed the decision in *Kohler* v. *Kohler & Chambers*. See, for example, *Ex parte Schaeffer*, 1896 C. D. 30; 76 O. G. 1118.

Directly in point is the decision of Commissioner Mitchell in *Mead* v. *Brown*, 1889 C. D. 173; 48 O. G. 397, which held that an applicant in a pending interference, who claimed to have been the sole inventor, is not estopped by reason of his oath in a preliminary statement in a previous interference, wherein he was one of two joint applicants, nor by the testimony of his witnesses in that interference, from correcting an error, if an error could be shown to exist, as to the date when his invention went into public use. The Commissioner says (p. 175):—

> "If it should be held that no consideration of justice, truth, or fact could avail to authorize the senior party to prove the actual date when the invention went into public use, then, if the fact should be otherwise than is asserted by the junior applicant, the latter might take a valid patent, while the earlier applicant would have been denied a patent because of the statutory bar of two years' prior public use. A method of administration which involves such a result must be a mistaken one, and I am compelled to the conclusion that under his present application, at some stage of the proceedings arising upon it, Brown is at liberty to show, if he can and if the office requires it, that his invention was not in public use for more than two

> years prior to his sole application. Such being the law, it follows that this is not a case in which an interference has been irregularly declared between one party who is entitled to a patent and another party who is forever estopped from obtaining a patent."

After citing the case of *Kohler* v. *Kohler & Chambers*, *supra*, the Commissioner continues (p. 176):—

> "It seems to me that the same principle is involved in the pending case, and that the party who claims to have been the sole inventor is no more estopped to correct an error, if an error can be shown to exist, as to the date when his invention went into public use than he would be to deny and correct his sworn statement that the invention was originally made jointly with another."

To the same effect see:—

> *Howard* v. *Haywood*, 1899 C. D. 8; 86 O. G. 184.
> *Saffert* v. *Mayer*, 1902 C. D. 30; 98 O. G. 793.

The case of *Union Mfg. Company* v. *Lounsbury*, 2 Fish. 389, cited by the defendant, is not in point.

In that case suit was brought on the reissue of a patent, the original of which and also a later patent for an improved machine had been given extended terms by Act of Congress. The reissued patent was for a process while the original patent was for a machine. The court found that the original patent was "invalid, because it did not and does not describe a practical invention" (p. 392).

The fact that the invention was imperfect was fully brought out in the hearings before Congress on the question whether the terms of the patents should be extended and it was because the Committee of Congress pointed out that "no inconvenience can result to the public, or injury

to any individual by the renewal in the extension of the first patent, because the invention was imperfect", that Congress somewhat illogically granted the extension of the patent in question.

Of course the plaintiffs having asserted before Congress as a ground for the extension of the patent that the invention was imperfect and the patent invalid could not in equity establish the contrary, namely that the invention was complete and the patent valid.

The case is one of many where the courts have held that parties can not enforce a right which they have expressly repudiated, their repudiation having been duly accepted and acted upon.

There are no such circumstances in the case at bar and the *Union* case is therefore not in point.

DEFENDANT'S ESTOPPEL CONTENTION IS CLEARLY UNSOUND.

We shall not take the time of the Court to do more than call attention to one or two incidental details of defendant's argument on this point. Defendant suggests that the old Thomson Company delayed the Rietzel-Harmatta Interference that it might have a longer period for working under the Rietzel patent before the interference was decided, thus apparently adopting our view, that as soon as the Rietzel people knew of the Harmatta application, they must have recognized that ultimately a controlling patent would be issued to Harmatta. There is no foundation for any such suggestion. The Rietzel people did nothing which resulted in delay except to move to dissolve the interference, which procedure is as common in Patent Office interferences as is a demurrer or motion to dismiss in suits at law. Rietzel's preliminary statements and affidavits caused no delay whatever. Nobody was de-

ceived by them and they were a mere part of the ordinary procedure of a Patent Office controversy.

Defendant also alleges as wrongful conduct on the part of the old Thomson Company that it developed a license system under the Rietzel patent under which it received royalties for using spot welding machines and to support this contention refers to a license agreement of August 3, 1912, between the Thomson Company and the American Electric Welding Company (Vol. III, p. 2019). But so long as the Rietzel patent was in force as a valid patent, the Thomson Company was entitled to such royalties and on August 3, 1912, the date of the American Company's license, it owned the Harmatta invention which it had acquired April 3, 1912, and the license was under every patent "that is now or may be hereafter acquired by the Thomson Company". This included the Harmatta patent and the license was a grant under the Harmatta as well as the Rietzel patent. Twelve other patents and applications were specially named in the license.

Defendant also calls attention to two suits brought by the old Thomson Company on the Rietzel patent against spot welding infringers; but at the time of those suits the Rietzel patent stood as a patent covering such infringers. Neither of these suits progressed beyond the pleadings.

It is respectfully submitted that there is nothing material in defendant's contentions as to Rietzel or the Rietzel patent or the relation of Harmatta or of the plaintiff's predecessor thereto.

The opinion of the District Court in this case (Vol. I, pp. 24–50) severally criticises the conduct of the plaintiff's predecessor, the old Thomson Company, as to the prosecution of the Rietzel patent, the prosecution and settlement of the *Rietzel* v. *Harmatta* interference, the purchase

of the Harmatta application and the disclaimer of the claims in the Rietzel patent, of the subject-matter of which, as we have above shown, Harmatta was the prior inventor. The Court even charges fraud in some of these matters. These criticisms and charges are absolutely baseless, as is shown by the history of the events as above stated. We will not take the time of this Court to discuss them further. It is sufficient to say as to the Rietzel disclaimer (Vol. III, p. 1824), that as Harmatta was the first inventor of the subject-matter of the claims in question it was necessary to disclaim them from the Rietzel patent. No charges of fraud have been advanced on behalf of the defendant in the lower courts in this case.

CHAPTER V.

THE BARNEY & BERRY CASE.

Defendant has charged, as far as we can see without any basis whatever, that the case of *Thomson Electric Welding Co.* v. *Barney & Berry, Inc.*, 227 Fed. Rep. 428, was collusive (Vol. II, p. 798). In that case the Harmatta patent in suit was held valid and infringed by the Circuit Court of Appeals for the First Circuit, reversing the decision of Judge Dodge of the District Court, who had held that the patent was invalid for lack of invention.

We deny most emphatically this charge. There is not the slightest evidence to support it.

That case was bitterly contested from start to finish. Even after the decision of the Court of Appeals, the defendant moved to reopen the case in order to consider an alleged new reference, the French patent to Bouchayer, which motion was denied (Vol. I, p. 8).

The answer in that case set up as anticipations of the Harmatta patent thirty-three United States patents, twenty-four British patents, one Austrian patent, five German patents and seven French patents, including all of the patents to which reference has been made in this case except the United States patent No. 574,942 to Robinson and the British patent No. 14,536 of 1894 to Parkinson. The process described in the Robinson patent is merely a variation of the process described in the Kleinschmidt United States patent No. 616,436, which was carefully considered by the Court of Appeals and adds nothing of consequence to the prior art. Parkinson's British patent is for glutting and contains no disclosure or suggestion of spot welding.

The defendant has also asserted that in the Barney &

Berry case the McBerty prior use evidence was "suppressed" (Vol. II, p. 751).

As we have already shown, the "McBerty prior use", which we have discussed fully, was thoroughly investigated in the fall of 1913 by Mr. C. V. Edwards, counsel for the defendant, Barney & Berry, Inc., and affidavits concerning it were obtained by Mr. Thomas Howe, who was associated with Mr. Edwards as counsel for the defendfendant, with the assistance and cooperation of McBerty himself. These affidavits have been offered in evidence in this case and vitally contradict McBerty's present testimony, as we have shown.

The facts are stated by Mr. Edwards, called as a witness for the plaintiff in this case (Vol. I, p. 290): —

> "*A.* I am very certain that there was absolutely no collusion in that case. Before the Barney & Berry suit was brought we had defended another suit for the Toledo Electric Welder Company brought against that company by the Thomson Company; that case was the Thomson Electric Welder Company or Thomson Electric Welding Company against the North & Judd Manufacturing Company, and I believe the Toledo Electric Welder Company was a nominal party also in the District of Connecticut. During the litigation and when the litigation on the Harmatta patent was threatened, Mr. Warren, the principal stockholder and active head of the Toledo Electric Welder Company, took me into his confidence as to the financial status of his company and consulted me frequently from time to time as to the best terms to be made by his company from the business standpoint of extending his business and the financial situation as regarding his ability to stand the litigation, and I believe that I was very closely in touch with everything of importance to the defend-

ant that happened throughout the entire period of the litigation on the Harmatta patent. I am certain that neither Mr. Warren nor anybody else ever intimated to me or to anyone on our side of the case that an honest and successful defense was not desired, and we were never limited or stinted or questioned as to the money spent on the defense. *We made the best defense we could.*

"*Q.* 9. Do you recall any negotiations for a settlement of the Barney & Berry case; and if so, what effect did that have upon the vigor of your defense?

"*A.* Negotiations for a settlement were in the air practically at all times. Mr. Warren, Mr. McBerty and representatives of another welder company, I think the Winfield Company, and another concern, Geuder, Paeschke & Fry, I think that is the name of the concern, met me at various times and expressed the thought that was often expressed to me by Mr. Warren, that it would be a good thing for the benefit of the welder industry if a license could be obtained under the Harmatta patent, and at various times we tried to bring that about. Every attempt failed, because generally the Thomson Company wanted too much in the way of royalty, at least more than the others thought they were willing to pay. There was never, however, any thought expressed by anyone that it would be desirable or safe to let the Thomson Company achieve a victory before settlement, because we all felt that if that happened the Thomson Company would either keep the field to itself or exact a prohibitive royalty and none of us felt like taking that chance. Certainly the possibility of a settlement never in the slightest degree diminished our effort to defeat the patent in the trial of the case. We did hope that a trial could be avoided, but never

for a moment allowed that thought to interfere with our preparation of the defense."

Judge Dodge in the District Court held that the Harmatta patent was invalid. This fact alone should be a complete answer to the scandalous charge that the parties conspired to sustain the patent.

As is so often the case, there had been negotiations for a settlement before the trial in the District Court in April, 1914. They came to nothing and did not affect the strictly adversary character of that trial. There is no evidence or assertion on behalf of defendant that after the trial which was in 1914, until the final decision of the courts of the First Circuit in 1916, there were any negotiations between the parties.

The purchase of the assets of the Toledo Company by the Thomson Company in 1916 after the final decision in the Barney & Berry case was the natural result of that decision holding valid the Harmatta patent in suit and ordering an injunction and account. The circumstances and negotiations which led up to that purchase are given by Mr. Farley, the present president of the Thomson Company, called as a witness by the defendant (Vol. II, pp. 809–814). The purchase was a transaction which was entered into upon at Mr. Farley's initiative, and it signalized and accompanied a change of policy on the part of the Thomson Company, which followed upon Mr. Farley's becoming president of that company in the summer of 1916.

Mr. Farley, as he testifies, had never even heard of the Thomson Company until the summer of 1916, and much less had he any knowledge of the Barney & Berry suit or of any previous negotiations with the Toledo Company for a settlement of that suit (Vol. II, p. 807). Upon acquiring stock control and becoming president of this com-

pany in 1916, Mr. Farley found it tied up by a contract with the Universal Company which put the sale of the spot welding machines entirely within the control of the Universal Company, the Thomson Company's only interest in the matter being in royalties; the new management concluded that the Thomson Company itself should undertake the manufacture and sale of the machines. But if this policy was to be pursued the Thomson Company would have to make a new arrangement with the Universal Company and would also have to acquire manufacturing facilities which it did not then have. As the Toledo Company did have such facilities, and the stoppage of its manufacture of spot welding machines would in the ordinary course of events soon follow the decision in the Barney & Berry case, the defense of which the Toledo Company had openly assumed, it was logical and obviously desirable for the Thomson Company, if possible, to obtain these manufacturing facilities. Accordingly, Mr. Farley opened negotiations both with the Universal Company to cancel the contract with that company, and with the Toledo Company to buy its plant and settle the litigation with it without an accounting. The negotiations were carried along simultaneously, one being dependent upon the other. Mr. Farley first got a 30-day option from the Toledo Company for the purchase of its plant. This was on November 2, 1916. He then made his contract with the Universal Company, giving that company stock in the new company to be formed (the plaintiff herein) to take over the spot welding business, and not until he had agreed with the Universal Company was he willing to take up the option with the Toledo Company, which he did later in November, 1916.

On the same date on which the Toledo Company's contract was signed, the Thomson Company made a separate contract with Mr. Warren, the general manager of the Toledo Company, by which it retained his services,

because of the advantage which his good-will with his customers would give and because it was believed that he could be of assistance to the Thomson Company in making settlements for royalties on account of infringing machines then in use.

The dealings with the Toledo Company and with Warren in November, 1916, had absolutely nothing to do with anything that had gone before, and were entered into at that time purely because it then seemed to the officers of the Thomson Company advantageous for them to obtain the manufacturing facilities of the Toledo Company and to have the services of Mr. Warren.

The defense in the Barney & Berry case was conducted by counsel of the highest reputation, experience and ability, who were unstinted in expense. Every point was contested, and none that gave promise was overlooked or neglected, and the case was actually won by the defense in the District Court. The decision of the Court of Appeals for the First Circuit sustaining the Harmatta patent in suit in that case is entitled to the full respect of this Court.

CONCLUSION.

For the foregoing reasons it is respectfully submitted that the decree of the Circuit Court of Appeals for the Sixth Circuit affirming the decree of the District Court dismissing the bill of complaint should be reversed and the cause remanded to said Courts with instructions to enter a decree for the plaintiff, holding the Harmatta patent in suit valid and infringed and ordering an injunction and an accounting as prayed for by the bill of complaint and awarding to the plaintiff its costs of suit.

FORD MOTOR COMPANY, DEFENDANT-RESPONDENT.

BRIEF FOR RESPONDENT

This is a suit in equity brought by Thomson Spot Welder Company, a Massachusetts corporation, plaintiff-petitioner (hereinafter referred to as plaintiff) against Ford Motor Company, a corporation of Michigan, defendant-respondent (hereinafter referred to as defendant) for the infringement of letters patent No. 1,046,066, granted December 3, 1912 (upon an application filed just nine years earlier, namely, on December 3, 1903), to Johann Harmatta, of the Kingdom of Hungary, assignor to Thomson Electric Welding Company, the predecessor of the plaintiff, for improvements in Electric Welding.

The Harmatta patent has once before been in litigation, namely, in a suit brought March 13, 1913, in the United States District Court, for the District of Massachusetts, by Thomson Electric Welding Company,

et al., against Barney & Berry, Inc. In that suit the patent was held invalid by the District Court, presided over by the Honorable Frederic Dodge, Circuit Judge; but, on appeal, Judge Dodge was reversed and the patent sustained. Both the opinion of Judge Dodge and the opinion of Judge Putnam, speaking for the Circuit Court of Appeals for the First Circuit, are reported in 227 Fed. 428. Barney & Berry, Inc., was only the nominal defendant in that case, the real defendant being The Toledo Electric Welding Company, of Toledo, Ohio, the manufacturer and seller of a machine of whose use by Barney & Berry, Inc., complaint was made.

After the decision of the Court of Appeals of the First Circuit, the present plaintiff, Thomson Spot Welder Company, was organized to carry on the spot welding business of the Thomson Electric Welding Company, and proceeded to attempt to impose upon the manufacturers and users of electric spot welding machines a very onerous licensing scheme, requiring, among other things, the payment of a royalty of $250, each year, per machine, and also an acknowledgment of the validity of the Harmatta patent.

The manufacture and sale to the public of spot welding machines, by others than Thomson Electric Welding Company, began as early as the year 1908, or more than four years before the Harmatta patent was granted, and as the use of metal as a substitute for wood increased by leaps and bounds, the availability of electric welding for the union of metal sheets and other metal parts became more and more appreciated, until it came to pass that almost every factory contained as a part of its equipment one or more spot welding machines. The attempt, therefore, of the

plaintiff to hold up the users of spot welders under the Harmatta patent raised such a storm of protest throughout the country, that an organization was finally formed called "The Welding Patents Investigating Committee," with a view to determining, first, the true position of Harmatta in the electric welding art, and secondly, to ascertaining whether the suit against Barney & Berry, Inc., had been adequately defended, or only defended in such a partial and half-hearted manner as was thought by the parties would result in the sustaining of the patent. Over four hundred of the makers and users of spot welding machines became contributors to a fund to carry on the work of this committee with the understanding that any contributor might avail himself of the materials of defense which the committee might gather. (See Defendant's Exhibit Bulletin, No. 21, July 17, 1917, offered at page 1001.)

The plaintiff itself realizing the weakness of its position, notwithstanding the adjudication of its patent, for a time adopted the policy of attempting by threats to extend its licensing field and of not risking the bringing of any suit outside of the First Circuit, until it finally discovered that there was such an increasing and general disregard of the patent as to require it to be further litigated, as the only chance of rendering it further profitable. The present suit, instituted December 1, 1917, over two years after the adjudication of the Court of Appeals in the Massachusetts case, represents the first attempt to judicially enforce the patent outside the First Circuit.

Notwithstanding its contribution of funds to the Welding Patents Investigating Committee, for the gathering of materials of defense, the defendant herein

has undertaken, at its own expense and without contribution from the committee or any of its members, to alone bear the whole burden of the defense of this case.

The very large record that is now presented to the Court for consideration represents, in part, defendant's efforts to enlighten the Court and to guide it to a correct conclusion as to the merit, or lack of merit, of Harmatta's contribution to the electric welding art.

It is believed that the record shows, among other things:

(a) That plaintiff's exploitation of the Harmatta patent represents but one effort, among many, on the part of plaintiff and its predecessor, to maintain their dominance in the electric welding art, notwithstanding the expiration of the fundamental patents of Thomson and others, covering generically, that art, as well as the specific application of it now called "spot welding."

(b) That plaintiff's predecessor made a prior notable attempt to control so-called spot welding through a patent granted to it in 1909 as the assignee of one Adolph Rietzel, one of its employees, and then after that patent had been used for over three years as the foundation of a licensing system and as a club to enforce the payment of tribute by users of spot welders, procured through purchase, the Harmatta United States application and transferred to that application all the broad generic claims of the Rietzel patent and took a new patent running in the name of Harmatta, which extended the plaintiff's monopoly seventeen years longer, making it twenty years in all.

(c) That Rietzel in his work conceived and reduced to practice two modifications of spot welding, involving in their practice the same method of operation and resulting in the production of the same article, namely,—

(1) The spot welding of superposed plates, one or both of which were formed with slight projections for localizing the application of pressure and current at separate or isolated spots; and

(2) The spot welding of plane-faced plates by the application of current and pressure at isolated spots by means of pin electrodes.

(d) That when, during the prosecution of the application for the Rietzel patent, the foreign patents of Harmatta were cited in anticipation of Rietzel, the Thomson Company, through the sworn affidavits of Rietzel, represented to the Commissioner of Patents that Rietzel's invention of both the process of spot welding plates having projections and the process of spot welding plane-faced plates antedated the invention of Harmatta as disclosed in said foreign patents.

(e) That, in an interference in the Patent Office that was ultimately declared between the Rietzel patent, and the U. S. application of Harmatta, the Thomson Company again, through sworn affidavits of Rietzel, represented to the Commissioner of Patents that Rietzel was the prior inventor over Harmatta, and, by virtue of such representation, an immediate judgment of priority against Rietzel was averted, and the Rietzel patent was enabled to be further continued to be used, unaffected, as the basis for the Thomson Company's licensing system and as a menace with which to threaten the public into submission to the Rietzel patent.

(f) That by reason of the representations so made to the Commissioner of Patents, as the representative of the general public, the plaintiff, as the successor in interest of the Thomson Electric Welding Company, is precluded and estopped to deny the priority of Rietzel in this suit against this defendant, a member of such general public.

(g) That, independently of the question of the plaintiff's estoppel to deny the same, Rietzel is shown by the proofs to have been, in fact, the prior inventor over Harmatta.

(h) That Fred P. McBerty, of Warren, Ohio, invented and practiced the so-called method of the Harmatta patent in the year 1901, or nearly three years before the earliest date that can be set up for Harmatta.

(i) That the practical art of spot welding in this country was developed from knowledge derived from the said McBerty's work in 1901, first, by one Albertus C. Taylor, in 1904, at the works of the Winfield Electric Company, at Warren, Ohio, and secondly, by one William E. Smith, in 1905, at the Ohio works of the Carnegie Steel Company, at Youngstown, Ohio.

(j) That Sebastian Ziani de Ferranti, of London, England, was also the prior inventor over Harmatta, of the subject-matter of the Harmatta patent.

(k) That the disclosure of the Harmatta U. S. application, as originally filed, shows no disclosure of anything new, either by way of method or product, in the electric welding art, but that, aside from certain

immaterial details of apparatus not claimed to be embodied in and covered by the Harmatta patent, said Harmatta application discloses nothing that was not well known and that had not been previously disclosed and described in prior patents and publications in this and in foreign countries and particularly in the prior expired patents to Elihu Thomson once owned by plaintiff's predecessor.

(l) That the only kind of metal plates specifically suggested by Harmatta, either in his United States patent or in his foreign patents, as susceptible of being united by his process, i. e., plates of tinned sheet iron (fer-blanc) was the identical kind of plates described by Thomson in his earlier patents which plaintiff now claims do not embody Harmatta's conception.

(m) That the Harmatta U. S. application, as originally filed, discloses nothing distinguishing Harmatta's suggestions from the prior art—

(1) As to the *kind* of metal plates to be united;
(2) As to the *material* of which the *electrodes* employed to apply the pressure and current are constructed;
(3) As to the size of the welds;
(4) As to the amount of pressure required to be applied;
(5) As to the amount of current to be applied; or
(6)As to the time or duration of the application of pressure and current;

(n) That the defense of the Massachusetts suit against Barney & Berry, Inc., was inadequate and partial, and that the evidence regarding the conduct of that case leads to the suspicion, at least, that the

result reached was due to the suppression of defenses known by both sides to be available and to such collusion between the parties to the suit as to deprive the adjudication in that case of any weight or value whatsoever in the determination of the issues in the present suit; and

(o) That, finally, the whole course of conduct of the plaintiff and its predecessors, with respect to the subject of spot welding, has been so unjust and inequitable as to deprive the plaintiff of the right to any relief in a court of equity.

The trial Court saw and heard the fact witnesses who gave testimony in regard to the McBerty defense; saw the McBerty apparatus operated in his presence, and after most careful consideration of the whole case, filed an exhaustive opinion sustaining the majority of defendant's contentions, and ordered the bill dismissed. From the decree entered by the trial Court an appeal was prosecuted to the Circuit Court of Appeals for the Sixth Circuit and the latter Court affirmed the decision below, sustaining specifically the defense of lack of invention, without going into the other defenses of prior invention, prior public use, estoppel, etc., also sustained by the trial Court.

ELECTRIC WELDING

The application of electricity as an aid in the welding together of parts or pieces of metal of various forms and shapes, adapted to various uses, has given rise to a terminology that is quite confusing to a layman and even to an expert.

In the testimony of witnesses given in this case, in

the prior patents relating to electric welding, and in the general literature of the art to which reference has been made, we constantly meet with such expressions as "arc welding," "resistance welding," "spot welding," "point welding," "projection welding," "electrode welding," "roller welding," etc. All these, however, refer to electric welding that may be classified as either, (1) Resistance Welding, or (2) Arc Welding.

In the standard publication of Hamilton & Oberg, entitled, "Electric Welding," these two classes are distinguished as follows (Rec., p. 191):

> "*Different Systems of Electric Welding.*
>
> The principle of electric welding is simple: the parts that are to be welded are heated to a welding temperature by means of an electric current. There are two ways in which the electric current can be utilized for heating to a welding temperature, and according to the methods used, two main processes or systems of electric welding may be distinguished—the electric resistance-welding process and the electric arc-welding process. In the former—the resistance-welding process—the parts to be welded are brought to a welding heat by the passage through them of an electric current of such voltage and amperage that the resistance to the flow of current is great enough to produce sufficient heat *at the points or surfaces to be welded*, so that, when the parts are brought together by a slight pressure, they will be joined by the fusing of the metal, that is, by welding.
>
> In the latter system—the arc-welding method—an electric arc is drawn between the two electrodes or between the work and one electrode. This arc is brought into such a position relative to the work that the heat from the arc melts the metal to be welded, and enables the parts to be united.

> There are various modifications of this latter process, but, in principle, the above description is correct."

This controversy has nothing to do with arc-welding, so we may dismiss from further consideration that sort of welding, simply calling attention to the Benardos & Olszewski U. S. patent No. 363,320 (Rec., p. 1030) as an exemplification of it.

THE THOMSON PATENTS 347,140 (REC., p. 1021) AND 347,141 (REC., p. 1026) OF AUG. 10, 1886

Prof. Elihu Thomson is justly entitled to the distinction of being known and regarded as the father of the art of electric resistance-welding.

On Aug. 10, 1886, he was granted two patents, viz., No. 347,140 and No. 347,141, the former claiming and covering the art or process, of resistance-welding, broadly, and the latter an apparatus for practicing that art.

Referring to the art patent, No. 347,140 (Rec., p. 1021), we find that therein Prof. Thomson, in his statement of invention said (p. 1, line 9, of the patent):

> "My invention consists in a novel art or process of and apparatus for forming joints between metal wires, bars, and the like by the agency of an electric current. This art or process I term 'Electric Welding.'"

Again (p. 1, line 30 of the patent):

> "Briefly, the new art, which I term 'Electric Welding' consists in bringing together with a certain pressure the *ends* of the wires, bars, etc., to be

jointed, and which pressure must be small, and can with my apparatus be regulated at will, and then constituting the abutted ends and a slight portion of the wire or bar on each side of such ends as the path for an electric current of great volume, but not necessarily of an electro motive force of more than a few volts (depending on the nature and size of the wire or bar). * * *

"Either continuous, intermittent or alternating currents of electricity may be employed."

In this art patent, Prof. Thomson illustrated the joining or welding together of various articles, that is to say in Figs. 1, 3 and 4, the *ends* of two round wires; in Fig. 10 the *ends* of two flat plates; in Fig. 11, the *end* of a round shaft to the *end* of a similar short shaft section connected to a flanged head; in Fig. 12, the *end* of a square shaft to the *end* of a smaller round shaft; in Fig. 13, the *ends* of a split ring; in Fig. 14 the *ends* of a split link; in Fig. 15, the *ends* of two light bars to the *end* of a thicker bar. The materials of the parts to be united, Prof. Thomson stated, might be "of copper and its alloys, iron, silver, gold, etc." (p. 1, line 23), or "brass, iron, steel, or German silver" (p. 1, line 96).

The parts to be welded were described as being held by electrodes or clamps (K K′) of good conducting material described in the companion apparatus-patent, 347,141 (Rec., p. 1026), as "of copper or other good conductor" (p. 1, line 76).

Some significance attaches to the fact that Prof. Thomson thus, in the early days, mentioned the practicability of electrically welding by his process sections of copper or of silver, as well as sections of iron, since it goes to show the thoroughness of his investigations and his full appreciation of the scope of his discovery at that time.

According to the tables issued by the Smithsonian Institute (Rec., p. 588), the resistivity of copper is 1.586, that of silver, 1.46, and that of iron, 8.85. Consequently, where Prof. Thomson used copper electrodes or clamps for the welding of iron pieces, his electrodes were of *lower* resistance than the work itself; where they were used for the welding of copper pieces they were of the *same* resistance as the work; and where they were used for the welding of silver pieces, they were of *greater* resistance than the work.

Throughout his art-patent, Prof. Thomson laid particular stress on the presence of pressure and fusing current *at the joint or point of contact between the articles being welded*, as constituting the gist and essence of his discovery. This is emphasized, for instance, in claim 1 of the patent:

> "1. The herein-described art of effecting union between two pieces of metal, consisting in holding the same in contact *at the point of union* and simultaneously passing a current of electricity through the *joint* of a power to fuse and unite the pieces, as and for the purpose described."

The desirability of having clean the contacting surfaces to be united and of the wisdom of employing in some cases a flux to better the union, was also fully appreciated.

Thus, the patent states (p. 2, line 35):

> "Of course, it is important that the wires shall be clean to insure contact, and though usually the joint is well formed without any flux, such as borax, there is no objection to its use in slight amount in certain cases. In such cases, after abutting the wires, a little moist powdered borax or other flux may be applied at J (the joint)."

(See Mr. Dyer's discussion of these patents, Rec., p. 548, *et seq*).

THE THOMSON PATENT NO. 396,015 OF JAN. 8, 1889 (REC., p. 1037).

On Jan. 8, 1889, Prof. Thomson took another patent, No. 396,015, in which he disclosed an application of resistance-welding for uniting the proximate contacting plane surfaces of overlapped *flat plates*, in contradistinction to uniting the *end surfaces* of plates, bars or rods, as described specifically in his original art-patent, No. 347,140, just considered.

This application of resistance-welding by Prof. Thomson to the welding together of the *proximate contact surfaces of flat plates* was, it is true, incidental to the main purpose he had in mind when he devised the method and apparatus disclosed in this patent 396,015. Such main purpose was to fuse and upset, by the simultaneous application of pressure and an electric weld welding current, ordinary metal rivet blanks applied through openings in overlapped metal plates. Prof. Thomson proposed that, instead of pre-heating rivets in the usual manner, and passing them, while hot through the plates to be united, and then heading them up, he would heat the rivets *in situ* by means of the electric current and upset them by the pressure of the same electrodes that fed the current to them. But in developing this idea, it occurred to him, quite naturally, that not only could the current be utilized to soften and upset the rivets, but could also be utilized to weld the surface of the body of the rivets to the surface of the walls of the rivet holes in the plates; and it then, also quite naturally, further occurred to him that he could, by the use of a proper form of electrode, pass

the welding current *directly through* the *plates themselves* and weld the *proximate faces of such plates together,* so that he would have an exceedingly firm connection between the superposed or overlapped plates, consisting, first, of the upset rivets; secondly, of the weld between the rivets and the walls of the rivet holes, and, thirdly, of welds *directly formed between the plates themselves at points more or less remote from the rivets and rivet holes.*

The patent states (p. 1, line 17):

> "In carrying out my invention I may swage or form both heads after the heating of the rivet-blank in position in the work, or may swage or form one head only, the rivet having been inserted with one head ready formed.
>
> "The heating of the rivet when in position may be carried only to the point sufficient to permit it to be set by swaging or heading its ends, or the current may be allowed to pass for a longer period and until the central portion of the rivet, as well as the metal near thereto, is raised to a welding temperature, when the application of pressure expanding the rivet in its seat will weld the same to the metal surrounding it, and the application of pressure to the pieces to be riveted will weld them together around the rivet.
>
> "*In some cases, I may cause the electric current to flow across from piece to piece of the parts to be riveted, as well as through the rivet itself.*"

Modified forms of apparatus by means of which the electrodes were caused to pass current through the plates themselves, to *thus cause welds to be formed between the proximate plane surfaces of the plates,* were shown in Figs. 9 and 10 of the drawings of the patent and were described in the specification of the patent

(p. 2, lines 50 to 87), and two illustrations of welds thus formed were portrayed in Figs. 6 and 7 of the patent drawings.

Mr. Dyer, defendant's expert, very lucidly analyzes this Thomson patent, No. 396,015 (Rec., pp. 548-551), and Prof. Thomson himself, when called as a witness for defendant, admitted, though reluctantly, that the patent disclosed the welding together of the plates themselves, face to face, in addition to the upsetting or welding in of the rivets passing through the plates, and that the patent claimed the method involving this. He was asked (Rec., p. 532):

> "Q. 26. Is not the idea of welding the plates themselves together, also given expression in the sixth claim of this patent, which reads as follows:
>
> '6. The herein described method of fastening two pieces of metal together, consisting in passing a heating electric current through a rivet or rivet blank passing through the pieces, *as well as through the pieces of metal themselves* in the neighborhood of the rivet, and applying pressure to set the rivet and weld the pieces together?'
>
> "A. Undoubtedly that is one of the objects of the patent, as clearly shown in Figs. 6 and 7, not only to heat the rivets, but in some cases to allow the current to heat the plates so that they might be involved with the rivet in a weld."

This answer well illustrates how self-interest will induce a witness of even Prof. Thomson's caliber to equivocate and attempt to mislead. By his adroit reference to Figs. 6 and 7 Prof. Thomson sought to give the impression that claim 6 refers to the practice

represented by those figures, but when we come to look at the specification of the patent for a description of those figures we find that the plates of those figures are heated by conduction of heat from the current-heated rivets and not by the passage of the current directly through the plates themselves, as called for by the claim.

THE THOMSON PATENT 444,928 OF JAN. 20, 1891 (REC., p. 1047).

Another application of electric resistance-welding is found disclosed in Prof. Thomson's patent No. 444,928, dated Jan. 20, 1891 (Rec., p. 1047).

There is no doubt about the purpose of the invention of this patent being to unite plane sheets of metal, face to face, by pressure and an electric welding current applied to the sheets to be united, the pressure being applied to the work through the electrodes that feed the current to the work, and *the welds being formed between the contacting faces of the work at the point of pressure, only.*

The patent states (p. 1, line 15):

> "My present invention relates more particularly to the process, of joining or welding together strips, sheets, plates, or bars of metal where it is desirable to form a joint of considerable length, and is especially applicable to the welding of plates together at their edges, *instead of riveting,* to the welding of ribs or strips of metals to plates for the purposes of strengthening the same, to the formation of pipes by welding a longitudinal joint, to the welding of half-round or other shaped strips on one or both sides of a plate or strip of metal, and to other similar classes of work, as will be obvious.

"My present invention consists essentially, of forming an elongated joint by the electric welding process by feeding the work in the longitudinal direction of the joint through suitable pressure devices, the work being properly arranged so that the pressure devices will press the surfaces to be welded together, and simultaneously passing an electric current through the work at the point of pressure."

The specific means disclosed as suitable to be employed in the practice of the application of electric resistance-welding disclosed by this patent were two roller electrodes (Figs. 1 and 3) or two electrode segments (Fig. 2), of good conducting material, means for pressing the rollers or segments toward each other so as to clamp between them, face to face, the plates to be united, and means for supplying a suitable welding current to the electrode rollers or segments.

The patent states (p. 1 line 66):

"The frames F F' being of conducting material, may be connected with any suitable source of electric current of large volume through cables C, C, or by other means, so that an electric current may be caused to pass from one roll to the other, and *through any pieces of conducting material held between them in pressure contact.*"

After thus stating that the current may be passed through *any pieces of conducting material held between* the rolls, the specification goes on to describe the specific application of the process shown in Fig. 1, wherein two plates, *overlapped near their edges,* are portrayed as being operated upon by two electrode rollers R. R'.

The specification states (p. 1, line 84):

> "The edges are slightly *overlapped,* as shown, and the plates, being in position between the rolls, may be squeezed together by means of the screw S, thus forming an electric contact between them. The electric current being now turned on as it passes from one roller to the other and across the *point of pressure* will heat the work to the welding temperature and soften the same slightly, after which the screw may be given a few more turns to effect a solid union."

So far, the specification has certainly described a typical instance of the welding together, face to face, of two flat metal plates by means of two current-feeding roller-electrodes applied with pressure to the backs of the plates, the plates being first squeezed together by the rollers to make a good contact between them, then subjected to the action of the welding current at the "point of pressure" between the two plates, and, then, further squeezed "to effect a solid union" of the plates at that point.

Whether the contacting surfaces of the roller-electrodes are, initially, at the extreme end of the overlapped plates, or slightly distant, or greatly distant, therefrom, the specification does not state, but whether at one place or the other is wholly immaterial. Whenever the roller-electrodes press upon the interposed plates, and current passes, they produce, inevitably, a welding of the proximate contacting surfaces of the plates, at an isolated spot, and each time the rollers are opened, the work fed and the rollers closed again, another weld, at another spot, is produced.

After describing the production of the preliminary weld, the specification of the patent goes on to tell us how a continuous seam may be welded, as follows (p. 1, line 94):

"The work, *having been thus started,* may now be moved along through or between the rollers, so as to bring *successive parts of the joint* into position to be pressed and heated at the same time.* By this operation the metal will become thoroughly united as it passes through and out between the rolls. It is obvious that the speed of the operation may be varied by varying the rate of heating and the rapidity at which the work may be fed through the rolls."

It is evident that Prof. Thomson thought he had made at least two advances in the art of resistance-welding by the disclosures of this patent, No. 444,928, namely, (1) broadly the union of two *overlapped plates* or pieces, *face to face,* at a spot, as distinguished from the union of two plates *end to end,* or abutted after the manner of his earlier patent No. 347,140, and (2) the union of two overlapped plates by a continuous seam.

The first, or broader invention, as expressed in the second claim of the patent, covers the making of the initial weld described by him preliminary to the production of a continuous seam, as follows:

"2. The herein-described improvement in forming electrically-welded joints, consisting in *lapping* the pieces to be welded upon one another, passing the lapped pieces through or between *suitable pressure devices forming the electrodes* of an electric heating circuit, and applying pressure to effect the weld."

This claim, it will be observed, is not limited to the use of roller electrodes, *any* "suitable pressure devices

*NOTE: Compare the statement in the original Harmatta specification respecting the action of his roller-electrode apparatus, i. e., "the pressure being exerted by roller-electrodes whereby *the advancing series of single points of the seam* to be welded is united to a whole with a minimum consumption of current" (Rec., p. 1358).

forming the electrodes of an electric heating circuit" being within its ambit; nor is it limited to the passing of the lapped pieces through the pressure devices, the insertion of such pieces *between* such pressure devices, in any way, being equally covered by it.

The narrower invention is covered by claims 1 and 3 of the patent, the former including the use of *any kind* of electrodes employed as "pressure devices," and the latter the use of *roller-electrodes* only.

Said claims read as follows:

> "1. The herein-described method of forming an elongated joint by the electric welding process, consisting in feeding the work in the longitudinal direction of the joint through *suitable pressure devices*, while properly arranged so that the pressure devices will press the surfaces to be welded against one another, and simultaneously passing an electric current through the work at the point of pressure.
>
> * * * * * * *
>
> "3. The herein-described improvement in forming longitudinal seams or joints between strips or pieces of metal, consisting in feeding the strips or pieces through *suitable rolls*, while arranged in proper position to be pressed together by such rolls, and at the same time passing a heating electric current from one roll to another and through the surfaces to be welded, as and for the purpose described."

Before leaving this patent, we would again call attention to the fact that its disclosures afford other examples of a process of resistance-welding in which the electrodes, being of high conductivity, offer a relatively low resistance to the passage of the current as compared with the resistance offered to the passage of the

current by the plates themselves and by the joint between the contact surfaces of the plates, thereby resulting in the generation of the requisite degree of heat, *at such contact surfaces,* to raise the same to the proper welding temperature.

A more extended discussion of the disclosure of this patent will be found in the testimony of Mr. Dyer, defendant's expert (Rec., pp. 551, 575, 582, 586, 597).*

THE LEMP PATENT NO. 553,923 OF FEB. 4, 1896 (REC., p. 1065).

A hypercritical comment has been made by plaintiff's experts upon the disclosure of the Thomson patent No. 444,928, last above considered, to the effect that the contact face of the roller-electrodes illustrated in Fig. 1 of the drawing of that patent are shown as extending clear across the lapped portions of the metal plates being operated upon, thus necessitating the making of a line contact between the plates from edge to edge of such lapped portions.

This criticism is, of course, entirely without force, as it cannot possibly affect the essential nature of the process whether the plates are brought into line contact across the whole or a part only of the width of the overlapped parts; but, at all events, the criticism, if there were anything in it, is fully met by the disclosure of patent No. 553,923, granted Feb. 4, 1896, to Herman Lemp,—a collaborator of Prof. Thomson's,—wherein, in Fig. 2, is shown what purports to be an exemplification of the previous Thomson invention, in which the pair of roller-electrodes *do not,* in their posi-

*NOTE: In the Barney & Berry suit Judge Dodge held this Thomson patent No. 444,928 to be an anticipation of the Harmatta patent.

tion of operation upon overlapped or superposed plates, extend way across the overlapped or superposed parts, *but only part way across.*

(See Mr. Dyer's discussion of this patent, Rec., pp. 552, 587, 599.)

THE THOMSON PATENT 496,019 OF APRIL 25, 1893 (REC., p. 1053).

In the early days of resistance-welding, Prof. Thomson was keenly alive to many and varied applications of it. In his lucubrations upon the subject he came to realize that he could unite by means of pressure and the electric current metal plates that were coated with a metal of lower fusibility than the plates themselves, as, for instance, plates of iron coated with tin. He evidently reasoned that if he could fuse or weld together the contact faces of thin iron plates themselves, as in his patent 444,928, he ought to be able to fuse or weld together the contact faces of such plates when surfaced with tin—a metal of higher resistivity though of lower fusibility than iron. See Table of Smithsonian Institution. (Rec., pp. 588, 589.)

He, accordingly, devised apparatus for carrying this idea into practice and disclosed the same in his patent No. 496,019, dated April 25, 1893.

In that patent he showed two ways of applying the resistance process in this new field, namely, one in which the tinned plates to be united were pressed together by electrodes of *iron or other metal* having a *lower resistance* than that of tin (the resistivity of iron being 8.85 and that of tin 13.0, Rec., p. 588), which would cause the fusing or welding temperature to be developed by the current, in greatest degree, in the tin coatings and at the joint between the inner con-

tacting surfaces of the coated plates; and the other, in which the tinned plates were pressed together by electrodes *faced with hard carbon,* which latter is a substance of *enormously greater resistance* than tin (the resistance of carbon being 720, while that of tin is as we have seen, but 13.0. Rec., p. 589), which would cause the heat developed at the joint to be supplemented by the heat developed by the resistance of the carbon faces of the pressure electrodes *at the backs of the plates,* such supplemental heat being transmitted, by conduction, through the plates to the inner faces or joint to be united.

In other words, Prof. Thomson found that in dealing with a metal of such high resistivity and low fusibility as tin he could, by the electric current, create heat sufficient to bring the tin to a fusing or welding temperature either (1) by using pressure electrodes of relatively *low* resistance (such as iron) and thereby develop the requisite temperatures *between the contact faces of the plates directly, at the joint,* or (2) by using pressure electrodes of relatively high resistance (such as carbon) to supplement the heat developed by the resistance of the joint by heat developed by the resistance electrodes at the backs of the plates, remote from the joint, and thus cause a proper fusion and union of the tinned faces of the parts at the joint.

In Figs. 4, 5 and 6 of the drawings of this Thomson patent, P. P′ indicate the tin-coated parts to be united and C C′ represent the pressure-electrodes of iron or other metal by which such parts are firmly pressed together and by which the fusing or welding current is fed to the work, developing, *directly at the joint,* the proper fusing or welding temperature.

Fig. 7 shows the modification in which the pressure

electrodes C. C′ of iron or copper are faced with carbon, as at F F′, so that there will be a large development of heat at the *backs* of the plates, due to the very high resistance of the carbon faces themselves and a transference of that heat *by the conduction of the parts P P′* to the inner tinned contact surfaces of the parts, at the joint.

While the patent does not show any specific means for holding the electrode blocks or pieces C C′ illustrated in Fig. 6, the specification writer, Mr. H. C. Townsend, was careful to state (patent, p. 2, line 10) that:

> "The clamping devices *and the means for regulating or controlling the current* may be such as are described in my prior patents Nos. 347,140, 347,141 and 347,142, or the clamping or pressure devices may be suitably modified, as to the shape of their clamping devices, when found desirable."

Referring to the above-mentioned Thomson patent 347,141, for instance (Rec., p 1026), we find that the clamping devices there shown are lettered K K′ (Figs. 1, 2, 3, 4) and are described as "made of copper or other good conductor" (p. 1, line 76); and that "suitable adjustments of current and elastic pressure are readily made *to suit the size of bars or wires and their conducting power*, so as to fuse or electrically weld them" (p. 2, line 10).

It should be carefully noted that the electrodes C C′ of Fig. 6 of the Thomson patent No. 496,019, now under consideration, are cut away at their end faces like the electrodes shown in Fig. 3 of the Harmatta patent in suit, and, also, that *such end-faces cover less than the whole of the proximate surfaces of the parts P P′ to*

be united, and, therefore, produce a weld that is entirely surrounded by an "area of unwelded union," such as is mentioned in the Harmatta patent (though not in the original Harmatta application).

In the modification of the electrode blocks shown in Fig. 7 of the Thomson patent, the blocks proper are said to be made of steel, or iron, or copper, faced with hard carbon (p. 2, lines 40 to 46); but, as carbon is fragile, the patentee says that he prefers not to use the carbon faces but to make notches or grooves in the faces of the metal blocks themselves so as to "leave only a series of points or ridges projecting" (p. 2, line 60), as shown in Figs. 8, 9 and 10; or, as an alternative construction, he provides the blocks with a series of projecting pins, as shown in Figs. 12 and 13.

Later, with reference to the forms of electrode pressure-blocks shown in Figs. 8 to 13, the patent goes on to state (p. 2, line 76):

> "In all these cases the conduction of heat away from the *pieces* held between the blocks is greatly checked by the form given to the surfaces as described, *and the resistance to the passage of the current at the work is increased* which in itself results in further production of heat at the sheet metal pieces *where pressed up together* between the conducting blocks C. C'."

Now, the merest tyro in this art can see that if the faces of the electrode contacts are thus caused to present a series of separated points, the current will pass through those separated points only, will cause a fusion or welding of the faces of the sheets opposite those points, only, and will leave areas of unwelded union between the areas covered by the points.

In the modification illustrated in Fig. 19 of the patent, there is shown the employment of roller electrodes having serrated co-operating faces. The speification says (p. 2, line 111):

> "The rollers exert pressure while the current heats the thin metal pieces *at successive points* between the rollers."

This heating of the thin metal pieces, at successive points, means, of course, the production of a succession of separated independent welds or unions at those separated points, and it shows clearly that Prof. Thomson had not only, at that early day, worked out the problem of producing a continuous welded seam by the use of smooth roller electrodes as disclosed in his previous patent No. 444,928, but had also developed the idea of forming a discontinuous or interrupted seam wherein the successive welds were separated from each other, *so as to leave areas of no weld between them.*

Coming now, to the last modification illustrated in this patent under consideration, namely, that shown in Figs. 21 and 22, we find there a disclosure of *pin-electrodes* arranged to weld and unite superposed metal plates *at places or spots considerably less in area than the area of the overlapped parts.*

Two views are given of this modified form of apparatus, to-wit, a front elevation (Fig. 21) and a cross-sectional elevation (Fig. 22). The co-operating electrodes are arranged in sets, each set comprising an upper electrode C and a lower electrode C'. These sets of electrodes are arranged vertically in a frame in which they are supported and guided. There is applied to each upper electrode a spiral spring, the stress

of which tends to keep it elevated and there is applied to each lower electrode a similar spring which tends also to keep it elevated. Initially the proximate ends of each pair of electrodes are separated, as shown in the case of the pair at the left of Fig. 21, so that the overlapped plates or parts to be united (shown in the figure as two flat plates) may be inserted between them.

For a further description of this form of apparatus and its mode of operation, we give the patentee's own language, viz. (patent, p. 2, line 115):

> "Fig. 1 shows how in one machine several sets of pressure pieces and current applying blocks may be successively operated, as where many pieces are to be operated upon in a given time. J to J′ is a series of cams on a shaft driven by a pulley D, belted to power. The cams are set to act successively on the plungers C, so as to depress them successively against the action of the springs which raise them. Corresponding lower plungers C′, insulated from the upper ones C, are arranged to be depressed in pinching or clamping the pieces between them. This is shown in Fig. 22, which is a view of one set only of the cams and plungers. I indicates insulation about plunger C′.
>
> After pressure has been exerted to clamp the pieces the continued depression of the plungers by the cam S brings the lower end of C′, at *a*, in contact with a current feeding plate below connected with a conductor K′, from the current source, the other conductor K running to the upper plungers, as C.
>
> The sequence of actions then is as follows:
>
> Pieces are placed between the plungers, pressure is applied by cams S, current passes through the pieces, when the plungers are fully depressed, current is cut off as plungers begin to rise, and

finally the pieces are released as the cam completes its revolution.

These actions occur respectively at different times with the different sets of plungers."

Here, then, we have, in this patent No. 496,019, disclosed, as the invention of the great Elihu Thomson—the father of the art of electric welding—the welding together, by pressure and electric current, of plates of tinned iron (*fer blanc*)—the only metal specifically mentioned anywhere in the various disclosures of Harmatta's work as intended to be acted upon by his process as we shall presently see—in five different ways, namely:

(a) By the use of electrodes (iron or other metal) of *lower* resistivity than the plates, so as to cause the maximum resistance, and, consequently, the greatest heating effect, to be developed *in the plates themselves and at the joints between the plates.**

(b) By the use of electrodes (iron or steel or copper, faced with carbon) of *higher* resistivity than the plates, so as to cause a greater resistance, and, consequently, a greater heating effect, to be developed in the electrodes *at the backs of the plates* and the transference, by conduction, of such heat through the plates to the joint to be there added to the heat developed by the resistance of the plates themselves and by the resistance to the passage of the current from plate to plate at the joint.

(c) By the use of electrodes (iron or other metal) of *lower* resistivity than the plates, provided with small,

*Mr. Gravell, plaintiff's expert, admits that where tools or electrodes of relatively good conductivity are used the resistance to the passage of current from electrodes to plates is relatively small, while the resistance of the plates themselves and between the plates, at the joint, contributes most to the generation of the necessary welding heat (Rec., p. 79).

separated projections through which the welding current is applied, at separated localized spots, to produce isolated welds, with areas of no union between them.

(d) By the use of (iron) roller electrodes, of lower resistivity than the plates, such rollers, having peripheral serrations or teeth which conduct the current to the work at separate successive points and, by thus localizing the heat, producing isolated welds with areas of no weld between.

(e) By the use of opposed pin (iron or other metal) electrodes of lower resistivity than the plates, having contact areas less than the areas of the overlapped plates acted upon, so as to localize the current *at spots* and make welds that are isolated and surrounded by areas of no weld.

In all these applications, the electrodes first clamp the plates with pressure, then the current is turned on, and then turned off, after which the pressure is relieved, all as described in the Harmatta patent.

The Thomson patent states that (p. 2, line 10):

> "The clamping devices and the means for regulating or controlling the current may be such as are described in my prior patents Nos. 347,140, 347,141 and 347,142."

The amount of current and the duration of contact and pressure are thus entirely within the control of the operator.

In regard to the character of the plates intended to be operated upon, the Thomson patent says (p. 3, line 12):

> "My present invention is especially applicable to use in uniting thin metals such as *tin plates*

without solder other than the tin on the surfaces, or with solder when found desirable."*

These and the other disclosures of the patent are discussed at length by Mr. Dyer, defendant's expert (Rec. pp. 553, *et seq.*, 575).

We would note, in passing, that while plaintiff's experts attempt to draw a distinction, in principle, between electric welding, electric brazing, and electric soldering, such distinction cannot be maintained, as shown by the following question and answer found in Mr. Dyer's deposition (Rec., p. 599):

"X-Q. 148. Do you recognize a well defined difference in principle between electric welding by what is sometimes called the electric resistance process, wherein the pieces are brought to welding temperature by the development of internal heat in them and an electric soldering process such as is described in the Thomson patent No. 496,-019?

A. No. I recognize no distinction in principle between the two, but regard the principle of one as precisely the same as the principle of the other, namely, the development of heat electrically in the neighborhood of the contiguous parts to be joined. I grouped the two processes in the same way that they are grouped by the Thomson Company, for instance, in the Lemp patent No.

*NOTE: It is interesting to note that while Harmatta in his original U. S. application, in his U. S. patent, in his Canadian application, and in his British patent, makes no mention at all of the kind of metal he proposes to weld; he does in his French patent, based upon the same identical apparatus, explicitly designate tinned iron (fer-blanc), three times—twice in the specification and once in the claims—as the metal to which his welding scheme is specifically adapted (Rec., pp. 1141, 1142, 1145, 1146, 1147).

It, therefore, does not lie in plaintiff's mouth to urge that the welding of tinned iron plates is not, exactly, the Harmatta invention!

> 553,923, which states that the invention relates to 'welding, soldering, cementing or similar operation.' The only difference is the necessary adjustment of current and time to secure the desired heating principle."

Mr. Dyer might have added that Prof. Thomson, in his so-called "Electric Soldering" patent, No. 496,019, groups electric soldering, brazing and welding together as belonging to the same class, thus (Rec., p. 1055):

> "My present invention, like my prior inventions in electric soldering, brazing and welding, involves the use of electric currents of low potential but large volume derived from any suitable source, together with suitable devices whereby the current may be cut off or regulated."

It has sometimes occurred to the writer of this brief that the title given the Thomson patent No. 496,019, *i. e.*, "Electric Soldering," represented an effort on the part of the specification writer (Mr. Townsend) to divert the mind of the Patent Office Examiner from the subject of electric welding to the subject of electric soldering with a view to giving the impression that Prof. Thomson's previous work in electric welding was quite different from his soldering scheme. The fact is, there is no true soldering described, with even fair particularity, anywhere in the patent, while the manipulation and electrical welding of tinned iron plates is specifically referred to throughout. If the writer of the Thomson specification had frankly described the invention as a process of electrical welding plates of tinned iron, as did Mr. Harmatta in his French patent No. 336,187, at a later date, when speak-

ing of the union of tinned iron (*fer blanc*) plates, he would have stated the truth and the Thomson patent would not have been open to this criticism.

THE ROBINSON PATENT 574,942 OF JAN. 12, 1897 (REC., p. 1070).

Other applications of electric resistance welding are disclosed in the Robinson patent No. 574,942, dated Jan. 12, 1897.

Robinson's purpose was to utilize the electric resistance-welding process in the production of railway joints.

One of the applications of this process shown by him was the welding of a fish plate or splice bar to the web of a railroad rail. In this embodiment of the process the fish plate or splice bar (C, Fig. 11) has formed upon its inner face at its upper and lower edges a series of isolated projections (i, i) which are adapted to bear against the plane vertical face of the web of the rail when the parts are pressed together by the electrodes that also supply the welding current.

The patent says (p. 2, line 92):

> "When the plate C is placed in the groove of the rail in position to be welded, these projections *i* find a bearing against the rail adjacent to the upper and lower corners of the groove of the same. The projections *i* are normally long enough to keep the main body of the plate C a short distance away from the rail. As soon, however, as the welding-current is turned on it quickly brings the projections *i* and the parts of the rail touched by them to a welding heat. The clamp is now applied to press the plate C and rail together to complete the weld as shown in Figs. 13 and 14."

The patentee points out that instead of employing the small projections on his fish plate or splice bar, he may use a series of ribs, as shown in the dotted lines, Fig. 16, but says (p. 3, line 20):

> "I prefer the arrangement of small independent projections to facilitate rapidity of welding, economy of current, and in order to have several small *welding spots* distributed over the rail rather than to have any single larger surface of the rail brought to a welding heat since the latter would be liable to deteriorate the rail."

The several other disclosures of this Robinson patent are discussed at length by Mr. Dyer (Rec., pp. 558-559), and the conclusion that he reaches is as follows (Rec., p. 559):

> "While, therefore, Robinson still makes use of the well known principles of resistance welding, he suggests the special refinement of welding the two pieces together in isolated spots (he calls them 'welding spots') which will be surrounded by very much larger areas of non-welding, and he localizes the welding current in these spots by providing projections or points which are traversed by the heating current and brought to the welding temperature, likewise heating the plates with which they contact to the welding temperature, so that when pressure is applied each projection so heated will constitute or form a single spot weld."

It is not amiss to add that not only did Robinson describe this application of the resistance welding to overlapped or superposed plates, but he made it the subject of several claims, a typical one of which is the following:

"8. In a rail joint a splice bar constructed for welded attachment to one only of the abutting rails, said bar being provided with a plurality of welding projections grouped nearer to one end of said bar than the other, said projections forming a plurality of welding connections with the same rail, the portion of said splice bar between said projections, and not raised to a welding heat, limiting the compression and regulating the predetermined relative position of said splice bar and rail when welded together, substantially as described."

THE KLEINSCHMIDT PATENT NO. 616,436 OF DEC. 20, 1898 (REC., p. 1076).

An application of resistance-welding very much like that of the patentee Robinson is found in the Kleinschmidt patent, No. 616,436 of Dec. 20, 1898.

Kleinschmidt, like Robinson, had in view the welding of splice bars to the webs of railroad rails. His patent shows in Fig. 2 a representation of his splice bar before welding. It is a bar that is generally plane-faced, but has a relatively low projection *b* near each end and a third low projection near the middle extending vertically across the face of the bar.

To secure the splice bars to the webs of the rails the bars were first clamped to the webs with their projections against the latter, by means of the circuit terminals or electrodes C, the welding current was then turned on and maintained until the parts were raised to the welding temperature, after which the current was turned off and the pressure retained until the parts cooled. As Kleinschmidt was dealing with parts of considerable mass, he laid much stress on the retention of the pressure on the parts after the cutting off of the current in order to make a more perfect union.

THE BURTON PATENT NO. 647,694 OF APR. 17, 1900 (REC., p. 1079).

Resistance-welding applied in many ways is disclosed by the Burton patent, No. 647,694 of April 17, 1900.

The patentee says (p. 1, line 9):

> "This invention relates to electric metal working apparatus for forging, welding and brazing of metals and for heating metal articles, such as wheel tires, for the purpose of setting them.
>
> "The invention is especially adapted for lap welding by the use of a primary transverse current. The lap weld is superior to the butt weld. *No end pressure* is required, and consequently, there is *no upsetting of* the metal and *no formation of a bulge or projection at the joint*, which is afterward required to be filed or hammered down."

The patent shows a rotary electrode head carrying on its various arms a variety of electrode tools adapted to co-operate with an electrode bed 100.

The mode of operation, where lap-welding is to be done, is described in the patent, as follows (p. 2, line 67):

> "In the use of this apparatus the pieces to be lap-welded are adjusted or placed with their ends overlapping on the bed electrode 100. Then the foot lever is depressed and one of the electrodes of the electrode head is brought into contact with the work, whereby the circuit is closed and the current passes through the work in transverse direction across the overlapping ends of the parts to be heated. The current may pass in either direction from the generator and effect the result

> equally well. As soon as the piece is heated to the proper temperature, which may be ascertained by inspection thereof, the operator releases the foot lever and the spring 170 lifts the hinged lever 150 and takes the upper electrode out of contact with the work, whereby the circuit is broken. Then the operator *may* shove the work forward on the anvil and hammer the joint or otherwise finish it, as desired."

Of course, if the parts worked are heavy, the joint may be improved by hammering on the anvil, but if they are relatively light this will not be required, nor done. The hammering step is plainly optional. It may or may not be resorted to.

Now, considering so much only of the prior art of electric resistance-welding as has been, so far, developed herein, it would seem perfectly obvious, even to a layman, that if the spherically ended electrode 240 of the electrode head of Burton should be brought around into operative relation with the flat copper bed electrode 100, and if the two pieces of metal to be lap-welded should be superposed or overlapped and placed between those electrodes and pressure and current applied and released, in accordance with the teachings of the patent and of the art, generally, the result would, inevitably, be a welding together of the two overlapped pieces, face to face, at a single isolated spot, and the weld so made would be surrounded by unwelded portions of the metal, in other words, a so-called, spot weld.

This is the view of defendant's expert, Mr. Dyer (Rec., pp. 560, 561, 577-579, 581, 587, 588, 605, 606, 607).

THE PERRY PATENT NO. 670,808 OF MAR. 26, 1901 (REC., p. 1083).

Another interesting example of resistance-welding is disclosed by the patent to Perry, No. 670,808, dated Mar. 26, 1901.

The welding together of crossed wires or of spherical bodies is described in this patent, whether these bodies be plain and uncoated, or coated with another metal.

When uncoated crossed wires are to be united they are crossed and pressed together in intimate contact by means of low resistance electrodes and the welding current is passed through until the contact surfaces of the wires are brought to the fusing or welding point, when the current is automatically cut off. The surfaces to be welded are, initially, but mere points of contact such as exist at the place where two crossed cylindrical bodies meet and touch each other, but the moment that pressure and current are applied, these points of contact, of course, flatten somewhat and the welded union really takes place between *small flattened surfaces* surrounded entirely by unwelded portions of the metal.

All the essentials of resistance-welding or, so-called, spot welding, with low resistance electrodes are, therefore, present. The bodies to be united are brought together face to face, instead of end to end; the low resistance electrodes are shaped to concentrate the current; the current is a welding current of high amperage and low voltage; pressure and current are simultaneously applied; and the current is automatically cut off.

The patentee says (p. 1, line 34):

"By my invention the welds are made instantaneously without any appreciable heating of the material adjacent to the point of the weld, and my improved method consists in the simultaneous application to the parts to be joined or welded of a mechanical pressure nearly equal to the crushing strength of the material and a current of electricity of relatively enormous volume. By using a mechanical pressure nearly equal to the crushing strength of the material, I insure the parts being forced together the instant they soften, and by the employment of a current of electricity of relatively enormous volume compared with the area of contact of the parts to be welded, I am enabled to produce an instantaneous heating or softening of the metal. The welding current is much stronger than has heretofore been considered suitable, being from one to two hundred thousand amperes to a square inch, while the mechanical pressure of the electrodes for forcing the heated parts together, is nearly equal to the crushing strength of the material being welded when cool. As a result of this the parts to be welded are first brought into intimate contact and immediately thereafter the circuit is closed between the electrodes. The current is of such strength that the contacting parts of the said members become heated to a fusing point immediately and as soon as the metal sufficiently softens, so that its resistance is less than the force of the compression spring or weight, such spring or weight forces the movable electrode farther toward the stationary electrode to weld the parts together. Immediately after this compression the circuit is broken and before the heat is spread away from the contacting surfaces. Consequently, the metal cannot be overheated or blown out. As the electrodes are relatively of large volume or area compared to the contacting metal to be welded, there is no necessity for artificial cooling."

THE PARKINSON BRITISH PATENT NO. 14,536 OF 1894 (REC., p. 1112).

Among the various industrial applications of resistance-welding disclosed in the prior art patents is the securing in place of the "glut pieces," so-called, to the arms or spokes of a metallic wheel. Each glut piece is a triangularly-shaped piece of metal whose inclined sides are adapted to fit between and against the correspondingly-shaped surfaces of two adjoining metallic segments or spoke-portions of the wheel.

The parts are clamped together by low resistance electrodes consisting, on the one hand, of a single electrode bearing against the base of the glut piece and, on the other hand, of two separate electrodes, one of which bears against the one segment-arm and the other against the adjoining segment-arm.

On pressure being applied and a proper welding current turned on, the resistance of the glut pieces (which is lower than that of the electrode) and the resistance offered to the passage of the current at the joint between the glut piece and the segment-arms, causes the proximate faces of the parts at the joint to be raised to a fusing or welding temperature. Continued pressure firmly unites or welds the parts together.

In the discussion of this Parkinson patent by Mr. Dyer, defendant's expert (Rec. pp. 565, 566, he says (p. 566):

> "In operation, when the contact piece M is forced by hydraulic pressure against the glut piece, the two contact arms or electrodes L will be pressed on the inside of the wheel opposite the glut piece, so that when heating current is applied it will flow from each electrode L through

the metal of the wheel, past the joint between the same and the glut piece and through the glut piece to the contact piece M. Each electrode L, therefore, feeds the current into the work in a limited area, and the current is, therefore, concentrated or localized by the electrode, so as to heat the metal at the joints and within a localized area to the welding temperature, whereby, under the hydraulic pressure, a limited isolated weld will be formed between each wheel segment and one of the glut pieces, which welds will be surrounded by extended areas of non-welding. This patent, therefore, discloses a further field of usefulness to which resistance-welding may be applied, namely, for the manufacture of railway or other wheels, it utilizes the same resistance principle originally disclosed by Prof. Thomson, in which the resistance of the work is depended upon to secure the heating effect, the current is localized and pressure is localized by means of an electrode of limited area, whereby the heating current is confined to a restricted path which cuts the joint and in this way the heating effect is localized or restricted, whereby the metal at the joint within a limited area will be brought to the welding temperature so that when pressure is applied between the parts an isolated weld will be secured, surrounded by areas of non-welding."

THE DE FERRANTI BRITISH PATENT NO. 11,921 OF 1903, FILED MAY 25, 1903 (REC., p. 1119).

A short description of the disclosure of this patent given by Mr. Dyer, defendant's expert (Rec. p. 567) will suffice, for present purposes (p. 567):

"I next refer to British patent to de Ferranti No. 11,921 of 1903, application for which was filed May 25, 1903, describing still another field of usefulness to which resistance-welding may be ap-

plied, namely the welding of turbine blades to the disks, drums or the like which carry them. Referring to Fig. 2, for instance, the disk or drum is shown as being provided with two sets of intersecting grooves *e* which result in the formation of a series of points or projections rectangular in cross section. The turbine blades *d* are now placed in position radially, and when heating current is passed through the blades the current will be concentrated by so much and so many of the projections as may make contact with the engaging surface of the blade, and by means of these projections the current will be concentrated so that the projections themselves, as well as those parts of the blade surface as may contact with the projections will be brought to the welding temperature, whereby, when pressure is applied a series of separate isolated welds will be formed surrounded by areas of non-welding. In Figs. 3 and 3a the same general principle is applied, except that the current is concentrated at the weld by forming the disk with two circumferential and parallel ribs, whereby two isolated welds will be formed to hold each blade in place. In Fig. 9a three of such ribs are shown, resulting in the formation of three isolated welds, and in Fig. 6 the face of the disk is bored with closely arranged holes *h* whereby the current will be localized by the metal between the holes and the resulting welds will be surrounded by areas of non-welding."*

THE GERMAN PATENT OF BENARDOS NO. 50,909 OF MAY 8, 1889, ISSUED FEB. 19, 1890 (REC., p. 1148).

The process of electric resistance-welding is also shown applied, in various ways, in the German patent of Benardos, No. 50,909 of May 8, 1889.

*NOTE: The claims of de Ferranti as a prior inventor over Harmatta, under Sec. 4887 R. S. U. S., and the International Convention, are discussed in the brief (p. 152).

Defendant has introduced a translation of this patent (Rec. p. 1152), made by Mr. Howard A. Coombs, of Washington, D. C. (Rec., p. 702), and plaintiff has offered another translation made by Mr. Walter Brant, of West Roxbury, Mass. They do not differ in any material respect.

Beyond any question, Benardos contemplated the welding of relatively thin plates of metal by the aid of electrodes which applied pressure and fed the welding current to the work at the point where the weld was to be formed. His dominant thought undoubtedly was to use electrodes of relatively poor conductivity and high resistance so as to develop heat in the electrodes themselves at the backs of the plates as in Thomson patent No. 496,019 hereinbefore considered. He contemplated both electric soldering and electric welding, for his patent states (Rec., p. 1152):

> "This process may serve to directly *weld* together relatively thin metal sheets and rods, of one and the same or of different metals; to the joining of metals with the use of a solder; to heating metal objects or parts to a definite temperature for the purpose of hardening them, and to annealing hardened objects by heating them to a certain temperature."

In the form of apparatus shown in Fig. 1 of his patent the current employed passes through his pressure electrode and thence through one only of his overlapped plates, the heat generated in the electrode itself being relied upon to raise the overlapped parts to the proper welding temperature.

In the form of apparatus shown in Fig. 6, the current does not pass directly through the work at all,

but merely through electrodes, each of which forms part of a separate circuit. The patent says (Rec., p. 1154):

> "Fig. 6 illustrates an apparatus which is distinguished from those hereinbefore described in that the current does not pass through the work itself."

The form of apparatus which is, however, of particular interest in this case is that shown in Fig. 2, which is described as follows (Rec., p. 1153):

> "Fig. 2 shows, in plan, elevation and end view, an apparatus designed to carry out the process in the manner just described. Two welding tools K′ K″, are united in the manner of a pair of shears or tongs, both being oscillatably mounted on the pivot C. The current is prevented from passing from one tool to the other through the said pivot by the interruption of insulating material. Binding screws D′ D″, receive the ends of the flexible cables connected to the poles of the source of electricity. The current thus flows from D′ through K′ to *w*′, from this block of refractory and poorly conducting material through the metal of the work to block *w*″, and returns through K″ and D″ and through a rheostat to the source of electricity. H′ and H″ are the wooden handles, and E is a spring by which the two blocks w′ and w″ are pressed together (apart)."

The patent mentions as examples of relatively bad conducting materials that may be employed as electrodes, graphite, prepared carbon, mixture of clay with carbon, magnesium, iridium, carbon with thin metal coatings (Rec., p. 1152).

Taking copper as a standard, all these enumerated materials are undoubtedly relatively poor conductors, yet some of them are better conductors than iron, of which the plates to be united are supposed to be composed, as the following table shows (Rec., p. 589):

Conductivity of	Copper.....	100.
"	Magnesium ...	36.2
"	Iridium	26.
"	Tungsten	28.8
"	Iron	17.9
"	Graphite	.195
"	Carbon	.22

The merest tyro in this electric resistance-welding art must appreciate that when electrodes made of any of the materials mentioned by Benardos as suitable, are employed to clamp the superposed metal plates and to feed the current through the work from one electrode to the other, as contemplated in the use of the apparatus of Fig. 2 of the patent, the current *must*, if it passes at all, encounter the resistance of the electrodes, the resistance of the joints between the electrodes and the backs of the plates, the resistance of the plates themselves, and the resistance of the joint between the inner contacting faces of the plates, and that wherever this resistance is encountered heat will be developed.

If carbon or graphite electrodes, or any other electrodes of low conductivity and high resistivity are used, to weld plates of higher conductivity and lower resistivity more heat may be developed in them than in the plates themselves, or at the contact surfaces between the plates, and a portion of the heat utilized at the place where welding actually occurs, namely, at the point of surface contact between the plates, may

be conveyed there by *conduction;* or, at least the heat generated at such point of surface contact between the plates will not be conducted away by such electrodes* whereas, if the electrodes used are made of magnesium or of iridium, or of carbon coated with metal, or of any other materials, whose resistivity is lower than that of the plates, the greatest resistivity and the consequent greatest heat development will take place in the plates and at the contact surfaces between the plates.

In any case, the contact of the electrodes with the plates will be restricted to a spot, the heating electric current will be passed from one electrode to the cooperating electrode through that spot to heat the work to the welding temperature and the pressure will be applied to the work in line with said spot to effect a

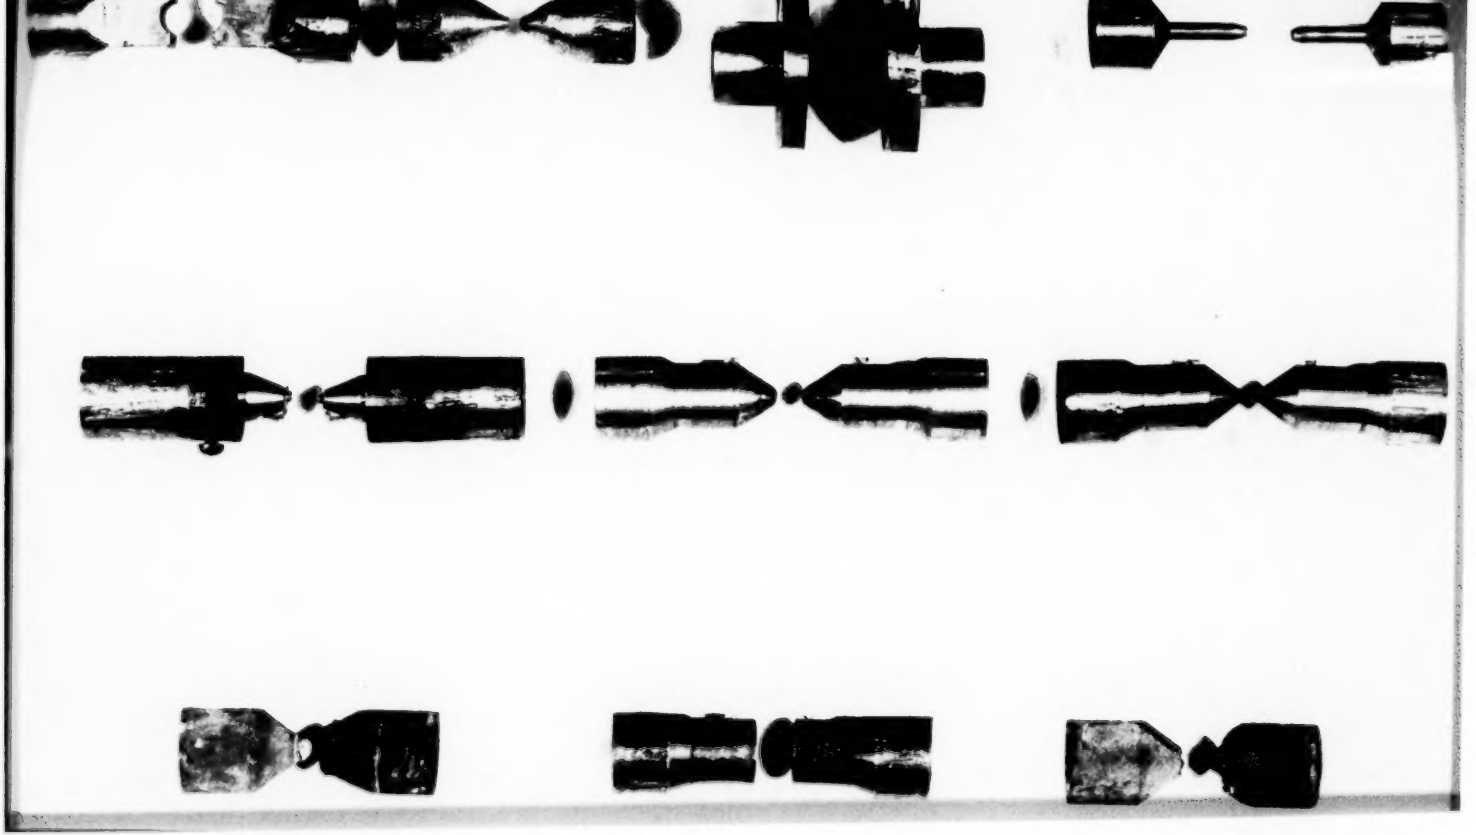
*NOTE: There will be found in the record (Rec., p. 2094) a copy of patent No. 1,176,614, granted March 21, 1916, to A. M. Stanley, assignor to the General Electric Company (by which Professor Thomson is now employed as consulting engineer) which describes the use of tungsten, molybdenum, or other metals of low conductivity and and high resistance as especially adapted to the spot welding of metal plates and particularly of plates of copper. The patent states (p. 1, line 85):

> "I have found that in order to successsfully weld sheet copper (which may here serve as the representative of low resistance and good heat conducting metals) it is necessary that the pressure contacts be of a material that has a considerably higher specific resistance than copper and that its ohmic resistance be sufficiently high that it may be heated by the current as much or more than the copper and then act as a barrier to heat conduction from the work; that it be a comparatively low conductor of heat for the same purpose; that it be *more refractory* than copper, so that it will not soften and become welded to the copper; and that it have considerable mechanical strength and not be noticeably deteriorated by exposure to air at the temperatures to which it is subjected. I have found all these characteristics combined in the metals tungsten and molybdenum, and by the use of either of them as pressure contacts, I have been able to weld together sheets of copper and other metals of like properties safely and expeditiously, and without deterioration of the contacts after long continued use."

welding of one plate to another, and the Harmatta process of so-called spot welding will be practiced.

Moreover, the work so produced will be metal work comprising a metal plate fastened on its surface to the opposed surface of another piece of metal by a weld at a spot only in the material of the opposed surfaces, said spot being surrounded by a distinct area of unwelded union, and will be the product of the Harmatta patent.

A detailed explanation of this Benardos German patent will be found in Mr. Dyer's deposition (Rec., pp. 563, 589, 608 *et seq.*, p. 611, *et seq.*).



Mr. Dyer testified to having made many tests demonstrating the practicability of producing, so-called spot-welds by means of carbon electrodes, graphite electrodes, electro-plated carbon electrodes (pp. 601, 612), iridium electrodes (pp. 601, 613) and offered in evidence photographs showing many of the forms of electrodes used by him (p. 612). (See photograph opposite, and explanation of same, Rec., p. 612.)

He also offered to repeat his tests for the benefit of plaintiff's counsel (p. 613).

This patent constitutes the finest kind of corroboration of the testimony of defendant's expert, Mr. Dyer, to the effect that electrodes composed of refractory material of low conductivity and of relatively high resistance, like some of those proposed by the Benardos German patent, are entirely available for the practice of spot welding. According to the official tables quoted by Mr. Dyer, the resistance of iridium mentioned by Bernados as available is 6.1 and its conductivity is 26, while the resistance of tungsten, the metal recommended by the Stanley patent, as highly available, is 5.57, and its conductivity is 28.8.

It is interesting to note that the Stanley patent discloses the use of tungsten for spot welding, both in the form of roller electrodes and in the form of pin electrodes, indicating that both forms are regarded as equivalents, by Stanley, just as they were apparently regarded as equivalents by Harmatta, in his original U. S. application.

As in view of the disclosure of the Stanley patent the Benardos apparatus would plainly spot-weld copper sheets, it is clear that Benardos is a clean-cut anticipation of Harmatta, who undertakes, in his U. S. patent, to cover the spot welding of *all* metals by any *sort* of electrodes, whether of high or of low resistance.

Mr. Gravell, plaintiff's expert, admits that carbon electrodes, coated with metal, will produce spot welds (Rec., p. 84).

The Application of Electric Resistance-Welding Here in Controversy Was Never Patentable to Harmatta.

The alleged process or improvement in the art that is here being exploited as the invention of Johann Harmatta never was an invention patentable to him, but is a mere obvious application of the principles of electric resistance-welding well known before his time.

Let it be distinctly understood that there is no patent for a machine or apparatus before the Court. The patent is, first, for a process, and, secondly, for an article made by that process.

The essential steps of the process are (1) overlapping or superposing two metal parts, face to face, (2) applying pressure and current to a portion only of such overlapping parts, (3) maintaining such pressure and current till the contact surfaces of the portions of the parts to which such pressure and current are applied are welded together at such contact surfaces only.

As a process, it differs from the process of the original Thomson art patent of 1886 only in the fact that the welding is localized in a relatively small contact spot instead of extending over the entire proximate surfaces of the parts to be united.

It is exemplified in the Thomson, so-called, riveting patent No. 396,015, wherein the plates are welded together in spots remote from the rivet; in the Thomson, so-called, roller-electrode patent No. 444,928, in

the Lemp patent, No. 553,928, and in Figs. 2 and 3 of the original Harmatta application wherein the overlapped sheets of metal are united, first, at a spot or part only and then at a succession of spots or parts; in the Thomson, so-called, soldering patent, No. 496,019, in which tin-coated iron plates are united in spots of limited area either by the localization of current between the plates or at the backs of the plates or at both places; in the Robinson, so-called, rail-joint patent, No. 574,942, wherein a plate formed with small isolated projections is welded to an opposing flat plate; in the Kleinschmidt, so-called, rail-joint patent, No. 616,436, wherein, also, a plate with isolated projections is welded to an opposing flat plate; in the Burton patent, No. 647,694, wherein overlapped plates are welded together in spots only by means of a spherically-shaped electrode, on the one side, and a flat co-operating electrode, on the other; in the Perry patent, No. 670,808, wherein crossed wires are welded together in isolated spots by the operation of opposed electrodes; in the de Ferranti British patent, No. 11,921, of 1903, wherein a turbine blade is welded in spots only to the blade carrier; in the Parkinson British patent, No. 14,536, of 1894, wherein the glut pieces are welded in spots to wheel segments by the application of opposed electrodes which apply the suitable pressure and current; in the Benardos German patent, No. 50,909, of 1889, and in the Harmatta patent in suit wherein overlapped sheets of thin metal having uninterrupted plane surfaces are welded in isolated spots by means of opposed pointed electrodes which apply the requisite pressure and current at the spots only; and in the Rietzel patent, No. 928,701, of 1909, wherein one or both of the sheets is or are pro-

vided with separate welding projections through which the pressure and current are applied.

Once we rid ourselves of the notion that this process or method is confined to the use of any specific form of apparatus or instrumentality, we will have no difficulty in apprehending just what the process in essence is.

On the folder opposite we have illustrated the various applications of resistance welding shown in the patents above referred to, whereby welding in isolated spots is accomplished.

Process Distinguished From Apparatus

This Court has always distinguished a process from the mere function of a machine or apparatus.

In the recent case of Expanded Metal Company vs. Bradford, 214 U. S., 366, the Court in reply to the contention that a process, to be patentable, must be the result of chemical or other similar elemental action, reviewed its former decisions and held that a process or method involving mechanical operations might be patentable, independently of the particular mechanisms for performing it.

Mr. Justice Day in delivering the opinion of the Court, said (p. 382):

> "An examination of the extent of the right to process patents requires consideration of the object and purpose of the Congress in exercising the constitutional power to protect for a limited period meritorious inventions or discoveries. Section 4886 of the Revised Statutes provides:
>
> " 'Any person who has invented or discovered any new and useful art, machine, manufacture or composition of matter, or any new and useful improvement thereof * * * may obtain a patent therefor.'

This is the statute which secures to inventors the right of protection, and it is not the province of the courts to so limit the statute as to deprive meritorious inventors of its benefits. The word 'process' is not used in the statutes. The inventor of a new and useful art is distinctly entitled to the benefit of the statute as well as he who invents a machine, manufacture, or composition of matter. The word 'process' has been brought into the decisions because it is supposedly an equivalent form of expression or included in the statutory designation of a new and useful art.

"What then is the statutory right to a patent for a 'process' when the term is properly considered? Curtis, in his work on the Law of Patents, says:

" 'A process may be altogether new, whether the machinery by which it is carried on be new or old. A new process may be invented or discovered, which may require the use of a newly invented machine. In such case, if both the process and the machine were invented by the same person, he could take separate patents for them. A new process may be carried on by the use of an old machine in a mode in which it was never used before * * *. In such a case, the patentability of the process in no degree depends upon the characteristic principle of the machine, although machinery is essential to the process, and although a particular machine may be required.' Curtis, 4th Ed., Sec. 14.

"In Robinson on Patents, Vol. 1, Sec. 167, it is said:

" 'While an art cannot be practiced except by means of physical agents, through which the force is brought in contact with or directed towards its object, the existence of the art is not dependent on any of the special means employed. It is a legal, practical invention in itself. Its essence remains unchanged, whatever variation takes place

in its instruments as long as the acts of which it is composed are properly performed.'

"And Walker on Patents, 4th Ed., Sec. 3, states that valid process patents may be granted for 'operations which consist entirely of mechanical transactions, but which may be performed by hand or by any of several different mechanisms or machines.'

"It is undoubtedly true, and all the cases agree, that the mere function or effect of the operation of a machine cannot be the subject-matter of a lawful patent, but it does not follow that a method of doing a thing so clearly indicated that those skilled in the art can avail themselves of mechanism to carry it into operation, is not the subject-matter of a valid patent. The contrary has been declared in decisions of this Court. A leading case is *Cochrane vs. Deener*, 94 U. S., 780, in which this Court sustained a process patent involving mechanical operations, and in which the subject was discussed by Mr. Justice Bradley, speaking for the Court. On page 787, that learned justice said:

" 'That a process may be patentable, irrespective of the particular form of the instrumentalities used, cannot be disputed * * *. Either may be pointed out; but if the patent is not confined to that particular tool or machine, the use of the others would be an infringement, the general process being the same. A process is a mode of treatment of certain materials to produce a given result. It is an act, or a series of acts, performed upon the subject-matter to be transformed and reduced to a different state or thing. If new and useful, it is just as patentable as is a piece of machinery. In the language of the patent law it is an art. The machinery pointed out as suitable to perform the process may or may not be new or patentable, whilst the process itself may be altogether new and produce an entirely new result. The process requires that certain things

should be done with certain substances, and in a certain order, but the tools to be used in doing this may be of secondary consequence.'

"This clear and succinct statement of the rule was recognized and applied (Mr. Justice Bradley again speaking for the Court) in the case of *Tilghman vs. Proctor*, 102 U. S. 707. In the course of the opinion the learned justice tersely says:

" 'A machine is a thing. A process is an act or a mode of acting. The one is visible to the eye—an object of perpetual observation. The other is a conception of the mind, seen only by its effects when being executed or performed. Either may be the means of producing a useful result.'

"That this court did not intend to limit process patents to those showing chemical action or similar elemental changes is shown by subsequent cases in this court.

"In *Westinghouse vs. Boyden Company*, 170 U. S. 537, the opinion was written by the same eminent justice who wrote the opinion in *Risdon Locomotive Works vs. Medart*, 158 U. S., *supra*, and delivering the opinion of the Court, he said (p. 557):

" 'These cases (158 U. S. 68, and 103 U. S. 461) assume although they do not expressly decide, that a process to be patentable must involve a chemical or other similar elemental action, and it may be still regarded as an open question whether the patentability of processes extends beyond this class of inventions.' And added these significant words:

" 'Where the process is simply the function or operative effect of a machine, the above cases are conclusive against its patentability; but where it is one which, though ordinarily and most successfully performed by machinery, may also be performed by simple manipulation, such, for instance, as the folding of paper in a peculiar way for the manufacture of paper bags, or a new method of weaving a hammock, there are cases

to the effect that such a process is patentable, though none of the powers of nature be invoked to aid in producing the result. *Eastern Paper Bag Co. vs. Standard Paper Bag Co.*, 30 Fed. Rep. 63; *Union Paper Bag Machine Co. vs. Waterbury*, 39 Fed. Rep. 389; *Travers vs. Am. Cordage Co.*, 64 Fed. Rep. 771. This case, however, does not call for an expression of our opinion upon this point, nor even upon the question whether the function of admitting air directly from the train pipe to the brake cylinder be patentable or not, since there is no claim made for an independent process in this patent, and the whole theory of the specification and claims is based upon the novelty of the mechanism.'

"And the same learned justice wrote the opinion of the court in *Carnegie Steel Co. vs. Cambria Iron Co.*, 185 U. S. 403, and sustained a process patent. If by any construction that process could be said to involve a 'chemical or other similar elemental action,' no stress was laid upon that fact. This court, speaking through Mr. Chief Justice Waite, sustained a patent in the *Bell Telephone Cases*, 126 U. S. 1, for a method of transmitting electrical undulations similar in form to the vibrations of the air accompanying vocal sounds, and at the same time the patent for the apparatus by which the method was operated was sustained.

In *Leeds & Catlin vs. Victor Talking Machine Company*, decided at this term, 213 U. S., 301, 318, this court said: 'A process and an apparatus by which it is performed are distinct things. They may be found in one patent; they may be made the subject of different patents.'

"We therefore reach the conclusion that an invention or discovery of a process or method involving mechanical operations, and producing a new and useful result, may be within the protection of the Federal statute, and entitle the inventor to a patent for his discovery.

> "We are of opinion that Golding's method was a substantial improvement of this character, independently of particular mechanisms for performing it, and the patent in suit is valid as exhibiting a process of a new and useful kind."

Applying the principles laid down in the above quoted decisions, we find that Harmatta did not invent the process or method of welding in spots, for that was old and well known before he entered the field and had been carried into practice by various forms of instrumentalities or apparatus.

He was not the first to conceive the idea of electrically welding overlapped or superposed metal plates or pieces at a relatively small contact spot instead of over the whole of their juxtaposed surfaces. Thomson, Robinson, Kleinschmidt, Benardos, Burton and others had done this before him, by the use of various forms of apparatus.

Even the forms of apparatus suggested by Harmatta for carrying into practice this process of welding in spots were not new. That form of apparatus which he elaborated with the greatest thoroughness and claimed most specifically in his application for patent as originally filed (and which, by the way, does not appear at all in the patent as issued) to wit, the form which involves the use of roller electrodes, was found by his solicitors to be anticipated, in substance, by the early Thomson and Lemp patents and, for that reason was jettisoned by them at an early day. His other form of apparatus, to wit, that involving the use of pin electrodes, is shown in the Benardos German patent of 1890, and in the Burton patent of 1900, which the Patent Office Examiner seems to have entirely overlooked.

All of the Process or Method Claims of the Harmatta Patent Are Anticipated and Void.

The method or process claims of the Harmatta patent read as follows (Rec. p. 389):

> "1. The hereinbefore described improved method of fastening two pieces of metal together by electrically welding them to one another at spots only of their juxtaposed or opposite faces by the application of pressure and heating current localized in such spots.
>
> "2. The herein described method of uniting two pieces of metal at a number of distinct or separate spots separated from one another by well defined areas of no union, consisting in applying pressure localized at the spots of desired union, and passing electric current through the pieces from one to the other while confining the flow of current to said spots until the union is effected.
>
> "3. The herein described method of uniting two pieces of metal, consisting in pressing them together while passing a heating electric current from one to the other and localizing the flow of current and the heating throughout the operation in a spot or spots of circumscribed or limited area as compared with the area of the immediately opposed surfaces, so as to limit the union of the pieces to a spot or spots.
>
> "4. The improved method of uniting two pieces of metal at a spot or spots only in their opposed meeting surfaces, consisting in pressing the two pieces together, and passing a welding electric current from one to the other while localizing the pressure in and confining the flow of current to the spot or spots of desired union so as to produce an isolated spot or spots of union, leaving distinct or well defined areas in which the pieces are not welded together.

"5. The method of uniting two sheet metal pieces together, face to face, consisting in pressing them together, and simultaneously with the pressure, passing an electric current from one to the other at isolated or distinct spots in the areas lapping or opposed, said spots being separated from one another by such a distance that there is a union of the sheets at spots entirely surrounded by the areas of no union.

"6. The method of uniting sheets of metals by pressing them together and at the same time passing a heating and welding current from one to the other at a spot on their meeting surfaces which is restricted in area throughout the operation so as to leave on the meeting surfaces a well defined and comparatively extensive area of no union completely surrounding said spot.

"7. The process of electrically welding thin metallic sheets, which consists in introducing the sheet metal parts to be welded between electrodes, pressing said electrodes firmly together and closing the circuit, whereby a small, sharply defined place of welding which answers the purpose of a rivet is obtained, substantially as set forth.

"8. The method of electrically welding two plates or sheets of metal together face to face between electrodes, consisting in restricting the area of contact of an electrode with said plates to a spot, passing a heating electric current from said electrode to the co-operating electrode through said spot to heat the work to welding temperature and applying pressure to the work in line with said spot to effect a welding of one plate to the other.

"9. The herein described method of producing a welding temperature in a small distinct spot or point of the opposed surfaces of two plates of metal, consisting in applying pressure at a point or spot only at the back of a plate coinciding with the desired point or spot of welding, while the plates are assembled face to face, to localize the

flow of current in the required point or spot in the meeting surfaces and passing an electric current through the plates in the line of the applied pressure to bring the material to welding temperature at the spot of welding by the resistance of the work to the passage of such current.

"10. The method of electrically welding a piece of sheet metal at a small distinct spot or point in its plane surface to the face of another piece of metal, consisting in applying pressure at a small point or spot on the back of the sheet to localize the pressure and electrical heating of the work at a spot of electrical contact in the opposed surfaces of said pieces beneath the point of applied pressure, and passing an electric current from one to the other at the said spot of localized electrical contact to produce a welding temperature at said spot and maintaining the localized pressure to effect a welding at said spot.

"11. The herein described method of welding two pieces of sheet metal together by a weld at a small spot only of their opposed surfaces, consisting in applying pressure localized in a spot on the back of a sheet directly over the desired spot of union, while said sheet is assembled face to face with the opposite sheet and so as to localize the pressure and electrical heating in a spot in the meeting surfaces of the sheets, and effecting the weld by passing an electrical current from one sheet to the other through said spot in the line of the localized applied pressure, and by pressure applied in said line.

"12. The method of electrically welding two pieces of sheet metal to one another, consisting in pressing the sheets together by pressure applied and localized in a distinct well-defined point or spot on the rear surface of a sheet while passing an electric current through them in the line of the pressure, thereby localizing the path of the heating current from one to the other of the meeting surfaces of the sheets to cause the said sheets

to be heated to welding temperature by the electric resistance of the work at said spot, and applying pressure localized over said spot whereby the pieces are welded together at a distinct well-defined spot in their meeting surfaces answering the purposes of a rivet.

"13. The method of electrically welding two plates of metal together face to face, consisting in pressing the plates together between two electrodes one of which at least makes contact with the rear of a plate at a spot only, feeding a heating electric current into the plates by said electrodes to bring the plates to welding temperature by the heating effect due to the electrical resistance of the portion of the circuit containing said plates, and effecting an electric welding of one plate to the other at a spot beneath the electrode by the pressure of said electrode.

"14. The herein described method of fastening two sheets of metal together at a distinct point or spot only in their plane meeting surfaces, consisting in pressing the sheets together and localizing the contact pressure of each upon the other at the said distinct spot or point, passing an electric current from one sheet to the other through said localized spot of contact pressure between them to bring the metal to welding temperature in said spot and thereupon completing the weld in the material so brought to welding temperature and uniting the pieces by a welded union at said spot only.

"15. The herein described method of fastening two pieces or sheets of metal together at a spot only in their meeting surfaces, consisting in pressing them together at said spot, passing an electric current through said pieces or sheets at said spot to raise the same to welding temperature and applying welding pressure localized in the back of a sheet immediately over said spot to effect the weld.

"16. The herein described method of welding two pieces of sheet metal together by pressing them together between electrodes engaging the surface of the sheets at a spot only and bringing the section of work between them to the welding temperature by its resistance to the passage of an electric current fed through the work by said electrodes."

Of these sixteen claims, the first six were taken bodily from the Rietzel patent. They were originally prepared by the astute counsel of the Thomson Company, after knowledge of the disclosures of the Harmatta foreign patents, to cover the spot welding of plane-faced plates or parts, as well as the union of plates or parts having pre-formed projections like Rietzel's, and they well accomplished that result.

Take claim 3, for instance, which reads:

"3. The herein described method of uniting two pieces of metal, consisting in pressing them together while passing a heating electric current from one to the other and localizing the flow of current and the heating throughout the operation in a spot or spots of circumscribed or limited area as compared with the area of the immediately opposed surfaces so as to limit the union of the pieces to a spot or spots."

But, unfortunately for the plaintiff, this claim not only applies to the disclosures of Rietzel and of Harmatta, but also to the disclosures of Thomson, Robinson, Kleinschmidt, Benardos and other prior workers in the art.

The same is true of the other method or process claims, as well those taken from the Rietzel patent, as those that were superadded after the termination of the interference with Rietzel to better cover Rietzel.

None of such superadded claims, however, expresses a patentable distinction over the claims taken from Rietzel, as examination will show. All of them are broad and all-covering and were intended so to be. Each reads upon the disclosures of Rietzel, and, by the same token, reads also upon the disclosures of Thomson, Robinson, Benardos, Burton, and others of the prior art and is anticipated and invalidated by the latter.

In this connection, the Court is respectfully referred to the very lucid discussion of the prior art by Mr. Dyer, defendant's expert. (Rec., pp. 546-614.)

PLAINTIFF'S ABORTIVE EFFORTS TO DRAW DISTINCTIONS BETWEEN HARMATTA'S PROCESS OR METHOD AND THE PROCESSES OR METHODS OF THE PRIOR ART.

Throughout their testimony the expert witnesses for the plaintiff have endeavored to draw distinctions between the process or method disclosed by Harmatta and that disclosed in the prior art, and to make out that Harmatta's process or method presents something radically new. But all such efforts are futile and will not bear analysis. They relate, in the main, to alleged differences in the apparatus or instrumentalities employed and the materials operated upon, and have no bearing at all on the questions of the novelty of the process or method, as such.

Some of these attempted differentiations will now be briefly discussed.

Roller Electrodes and Pin Electrodes

(1) On this point, it is first to be observed that Harmatta himself in his United States application,

as originally filed, as well as in his Canadian application, and in his British (Rec., p. 1124) and French (Rec., p. 1144) patents, draws no distinction at all between the process or method practiced by the use of pin electrodes and that practiced by the use of roller electrodes. He tells us that his electrodes, whether of one form or the other, may be made to approach and recede from each other, at will, so as to apply pressure and current to the interposed metal plates or parts to form the welds. With his roller electrode apparatus it goes without saying that he may either weld a continuous uninterrupted seam or, by opening and closing the rollers and shifting them, or the work (both methods are indicated as practicable in his original disclosure), he may make welds at distinct isolated spots as far apart as desired, having areas of no weld between them.

Defendant's expert, Mr. Dyer, says this may be done, and plaintiff's expert, Mr. Gravell, admits it. (Rec., p. 104.)

Harmatta, in his original United States specification, fully appreciated that the use of roller electrodes involved no essentially different operation, nor the consumption of any more current, than the repeated use of straight pin electrodes, for he says (Rec., p. 1358.):

> "Fig. 2 is a front elevation and Fig. 3 a side elevation of a device which may be employed for continuous welding, the pressure being exerted by roller electrodes, whereby the *advancing series of single points* of the seam to be welded is united to a whole with a minimum consumption of current."

(2) The prior Thomson patent No. 444,928 (Rec., p. 1047), and the prior Lemp patent, No. 553,923 (Rec., p.

1065), both show roller-electrode welding apparatus in which the electrodes are, and are intended to be, adjustable toward and from each other, the same as in the Harmatta roller-electrode apparatus, and the same capacity to weld continuously by an "advancing series of single points" or at separated points or spots, is found in all of them. The Thomson patent, as we have seen, tells us that, first, one spot is welded and then, thereafter, a continuous welding takes place (Rec., p. 1048, bottom of column 2), the language used being "so as to bring successive parts of the joint into position to be pressed and heated at the same time."

As instrumentalities for practicing the process or method of, so-called, spot welding, the roller electrodes are, therefore, as competent as straight pin-electrodes.

Whether or not it be claimed for Harmatta that the devising of his pin-electrode apparatus involved a mechanical improvement or improvement in *apparatus*, it certainly cannot be justly contended that the use of such pin-electrode apparatus involved the practice of a different art, process or method from that involved in the use of a roller-electrode welding apparatus whose rollers were openable and closable, at pleasure, on the work.

Plaintiff's counsel, in the early stages of the case, tried to establish that the use of roller electrodes in a welding apparatus was entirely impracticable, but the testimony on both sides turned out so overwhelmingly against them, on this point, that they probably will not renew the contention again. (Dyer, Rec., p. 583; Gravell, Rec., pp. 103, 104, et seq.; Knapp, Rec., p. 221; Knapp, Jr., Rec., p. 233, et seq.; Clark, Rec., p. 263; Thomson, Rec., p. 533.)

But to Harmatta does not belong the distinction of even having first devised a pin-electrode apparatus. The German patent to Benardos (Rec., p. 1152), and the United States patent to Burton (Rec., p. 1081), show such form of apparatus employed to electrically weld, at spots, overlapped or superposed plates or pieces of metal by a process or method identical with that claimed by Harmatta.

As to the form of pin-electrodes, much has been said in the testimony offered in behalf of the plaintiff in regard to the merits of pin-electrodes with pointed ends. In Figs. 1 and 2 of the Harmatta patent the electrodes happen to be shown pointed but in the actual practice of spot welding two (2) pointed electrodes are seldom used except to weld tin and like metals of low fusibility. Figs. 3 and 4 show electrodes of other forms. The machines brought from Germany in 1904 and installed at the factory of the National Enamelling and Stamping Co., and claimed by plaintiff to be Harmatta machines, though not proven to be such, had electrodes of uniform diameter throughout, with blunt ends (Knapp, Rec., p. 129; Herring, Rec., p. 132).

If there is anything in tapering or rounding the ends of electrodes the Burton patent and the German patent of Benardos show it (Rec., p. 1151), and these antedate Harmatta.

Thickness of Plates or Parts Operated Upon

Now and again in the testimony offered by the plaintiff will be found glowing tributes to the capacity of Harmatta's pin-electrode apparatus to unite by welding in spots, very thin sheets of metal. But these are tributes to *apparatus* and not to process or

method. The same process or method is involved in the use of any roller electrode apparatus, whether of Harmatta's invention, or of the invention of Thomson or of Lemp or of anybody else upon plates of *any* thickness. The thickness of the plates operated upon has, therefore, nothing to do with the novelty of the broad process or method under discussion.

That process or method, as shown by the evidence on both sides, is applicable to the union of metal plates or pieces regardless of their thickness.

Mr. Dyer testified he had successfully spot-welded a cold-rolled steel plate 1/32 of an inch thick to a 1/2 inch bar (Rec., p. 603). Mr. Gravell, plaintiff's expert, admitted that the Harmatta patent is not limited to the welding of plates or pieces of any specific thickness (Rec., p. 77); that he has seen plates 3/8 of an inch thick spot-welded together (Rec., p. 79, X-Q. 78) and that theoretically there is no limit to the thickness of material that may be spot-welded (Ibid, X-Q. 80). Prof. Thomson testified to the spot welding of plates of from 3/8 to 1/2 inch in thickness (Rec., p. 541). The catalogue issued by the Universal Welding Co., licensee of plaintiff's predecessor marked Defts. Ex. 10 says: "We can spot weld any gauge of material from the lightest gauge up to one inch thick." There was not in the United States application of Harmatta, as originally filed, any limitation placed on the thickness of the plates that could be successfully welded by the Harmatta apparatus, of either form. Nor does any such limitation appear in the Harmatta patent as granted.

During the prosecution of his United States application, when it was doubtful whether, even in view of the very limited prior art that had been cited by the Examiner, any novelty whatever could be found in

Harmatta's disclosure, an amendment was filed limiting the scope of the Harmatta invention to an apparatus for the union of sheets of "from about two millimeters in thickness downwards" (Rec., p. 1375) though there was no such limitation suggested in the original Harmatta application. Two millimeters is about 2/25 of an inch.

In the interference that was subsequently declared between Rietzel and Harmatta, it was stoutly contended by the plaintiff's predecessor, then the owner of the Rietzel patent, that such limitation was an admission that the spot welding of plates or sheets of more than two millimeters in thickness was NOT of Harmatta's invention and, consequently, an admission that the broader claims made for Harmatta and involved in the interference were claims that Harmatta was not entitled to make and to which he had made no oath of invention. (See brief of Rietzel, Rec., p. 1860.)

This contention was overruled, with the result that, as above indicated, the patent issued to Harmatta without any limitation as to the process or method being confined to the union of plates or parts of any specific thickness. We make mention of this matter here, to show upon what a narrow basis the alleged invention of Harmatta was once supposed by plaintiff's predecessor to stand.

However, all that may now be urged as to the adaptability of the Harmatta process to the union of extremely thin and flexible sheets of metal is quite beside the mark, since the matter in controversy is a process applicable, broadly, to plates or pieces of whatever thickness.

Moreover, the processes disclosed in the prior patent to Thomson, Lemp, Benardos, Burton, and others, are stated to be specifically applicable to the union of

thin sheet metal plates. This is especially true of Thomson, who, in his patent, No. 496,019, speaks of the use of his apparatus to unite *thin* tinned iron plates (Rec., p. 1055), and of Benardos, who in his patent says his "process may serve to directly weld together relatively *thin* metal sheets," etc. (Rec., p. 1152.)

Character of Current

Harmatta nowhere specifies the kind of current he intends to employ. It is *assumed* that he contemplated using a current of large quantity and low tension, as such a current is proper for welding.

Thomson, Robinson, Kleinschmidt, Burton and Benardos were, however, careful to tell us the kind of current they employed, being in this respect specific, where Harmatta is silent.

Electrode Materials

Harmatta nowhere tells us of what materials his electrodes—whether pin or roller—are to be made—whether of high or low resistance substances. If for the practice of, so-called, spot welding, necessity exists for the use of electrodes of any given material, he does not disclose it.

If necessity exists for the use of electrodes of relatively low resistance, instead of relatively high resistance, he does not disclose it. If necessity exists for the employment of electrodes whose resistance bears any special relation to the resistance of the parts to be united, he does not disclose it. If necessity exists for the use of electrodes that do not heat or heat much he does not disclose it. If necessity exists for effecting the welding by heat developed by the internal resistance of the parts to be united alone, instead of partly

in the electrodes themselves, he does not disclose it. If necessity exists for effecting the welding by heat developed principally at the joint between the parts to be united, he does not disclose it.

If the welding of metal plates can be effected by the use of electrodes of relatively high resistance (and the Thomson patent, No. 496,019, the Benardos patent, No. 50,909, the Stanley patent 1,176,614 and the uncontradicted tests of Mr. Dyer demonstrate that it can) (Rec., pp. 565, 601, 613), then the Harmatta patent hasn't a leg to stand on, for it gives no indication of any particular resistivity, relative or otherwise, and, in the absence of any directions on this subject, the use of all electrode materials must be held to be within the scope of the disclosure.

The above observations have relation to the disclosure of Harmatta's application as originally filed, which, alone, he swore to, as embodying what he claimed to be his invention. Any substantive matter introduced afterward by amendment and without his sanction and oath is, of course, without value.

The folder found opposite this page is inserted to illustrate, graphically, the relative resistances and conductivities of the electrodes and of the work in the Thomson patent No. 496,019, the Benardos German patent, the Harmatta French patent, the Stanley patent, and in the Harmatta U. S. patent in suit. It will be seen that where electrodes of high resistivity and low conductivity are used to weld plates of lower resistivity and higher conductivity, the disclosures of Thomson (Fig. 7) and of Benardos and of Stanley correspond, and that where, on the other hand, electrodes of low resistivity and high conductivity are used to weld plates of higher resistivity and lower conductivity, the disclosure of Thomson (Fig. 22) and of Har-

matta French patent, with iron or copper electrodes, and of Benardos, correspond. It will also be seen that the resistivity and conductivity of neither electrodes nor plates are given in the case of the Harmatta U. S. patent, the materials of these parts being undisclosed in the patent.

Materials to Be United By Welding

Turning to the original application of Harmatta, as filed, we find that he refers to the welding of "metal articles of all kinds in particular those of thinner sheet metal"; to "two metal sheets of equal thickness"; to "two sheet metal or other bodies"; to "sheets of metal only at particular places"; to "two superposed sheet metal ends"; to "thin vessels which are required to stand great pressure"; to "objects to be welded." But he nowhere tells us what kind of sheet metal he proposed to weld.

The absence of any particular designation in this regard would seem to indicate that the welding of all kinds of sheet metal would fall within the scope of his conception. This would, of course, include sheets of tin or of tinned iron. If sheets of either of these materials (which are of low fusibility) were employed, then electrodes of graphite or carbon, such as suggested by Benardos, in his patent 50909 or by Thomson in his patent No. 496,019, would suffice to fuse the surfaces of the sheets at the points of contact and result in perfect welds, and would fall within the claims in question.

In this connection, it is to be noted that in the Harmatta (Egel) French patent of October 13, 1903 (Rec., p. 1140), the welding of sheets of tin (tinned iron) is thrice referred to, and no other metal is mentioned as follows:

Original (p. 1141)

"Ansi que le montre la fig. 1, on introduit les deux corps metalliques (*fer-blanc* ou autre) dont les extremites se recouvrent, entre les deux electrodes a b."

Translation (p. 1145)

"As shown in Fig. 1 the two metallic objects (*tin* or the like) are introduced with their ends overlapping between the two electrodes *a* and *b*."

Again,

"Si alors on amene, par example, deux extremites de *fer-blanc* qu'il s'agit de souder et quie se recouvrent reciproquement entre les electrodes," etc.

"If then, for example, two ends of sheet *tin* which are to be welded and which overlap each other, are placed between the electrodes," etc.

And, again, in claim 2, as follows:

(p. 1142)

"2° Deux electrodes en ferme de galets, tenons ou autres, entre lesquels on introduit les objets a souder (*fers-blancs* ou autres), dont l'une puet etre raprochee ou ecartee de l'autre au moyen d'un levier, excentrique ou autre dispositif, actionne par une cremaillere ou autre dispositif."

(p. 1146)

"2. Two electrodes in the form of rollers, pins or the like between which are introduced the objects (*sheet tin* or the like) to be welded, one of which electrodes may be approached towards or separated from the other by means of a lever, eccentric or other device, actuated by a rack or other means."

The term "fer-blanc" occurring in the text of the French patent (ibid, pp. 1141, 1142) has been rendered "tin" by Mr. Coombs in his translation (Rec. pp. 1145, 1146). It really means tin plate or tinned iron;

but in common parlance, we refer to tin plate or tinned iron as "tin." For example, we speak of tin plates, tin cups, to designate tin-coated iron plates or cups; or we say "tinned goods," meaning food put up in so-called "tins," e. g., receptacles made of tin-coated or tin-plated iron.

The French word for pure tin is "etain."*

It is certainly very significant to find the French patent specifically mentioning tinned iron only, as the material proposed to be welded, since it indicates that electrodes of relatively high resistance, such as indicated by Thomson in his patent No. 496,019, or by Benardos in his patent No. 50,909, would be competent to carry out, and be well within, Harmatta's conception.

On the sound principle of patent law, that what would be an infringement, if later, would be an anticipation, if earlier, the Harmatta claims clearly cover, and just as clearly are anticipated by, the disclosure of the Thomson patent No. 496,019, which shows iron electrodes or carbon-faced copper electrodes, employed to electrically weld the tin-coated iron plates mentioned by Harmatta.

We do not, of course, know what the fact was, but we venture the suggestion that the two machines that were imported from Berlin, in 1905, by the National

*"*Heath's French Dictionary*," D. C. Heath, Boston, 1903. Tin, n. (Chem.) étain; (sheet iron coated with tin) fer-blanc.
Fer-blanc N. M. (-s-s) tin, tin plate, latten.
"*Mothes' Dictionnaire Technologique*," Wisbaden, 1874. Etain—tin. Fer-blanc m.—tinned iron-sheet, tin plate.
"*Spiers & Surrennes* French and English Pronouncing Dictionary," S. Appleton, N. Y. 1915. Fer-blanc n.m.—tin plate; tin; latten.
"Clifton & Grimaux," Library Garnier, Paris, 1914. Fer-blanc s. m.—tinned iron; tin-plate; tin; a thin plate of iron coated with tin.

Enameling & Stamping Co., were procured, primarily, for the purpose of welding tinned iron.

Mr. Knapp, the Director General of the company, testified that "The ordinary welding in a tin factory is just as *strong* as the ordinary riveting that has been done heretofore" (Rec., p. 128, X-Q. 55); but he then went out of his way to take a slap at the welding of tin ware, saying:

> "To weld tin ware it makes a black spot and burns the tin and in sheet iron or sheet steel it does not make that spot. The extreme heat at which welding is done does not interfere at all, where it would burn tin." (*Ibid*, p. 128, Re-D. Q. 57.)

It may be that in the welding of tin ware, when unskilfully done and without a proper regard to the strength of current used, the work might sometimes, as Mr. Knapp suggested, show a discoloration, but that would affect the appearance and not the strength of the weld.

When Mr. Knapp went out of his way to criticise the welding of tin ware, he evidently had not heard of the Harmatta French patent, and, therefore, did not know he was condemning the only specific application of electric welding—the welding of tinned iron—to be found in any of the Harmatta disclosures!*

---

*The spot welding of sheets of tin or of tin-coated iron presents no difficulty.

In the standard publication entitled, "Electric Welding," by Hamilton & Oberg, under the title "Spot Welding," occurs the following statements (p. 95):

> "Tin can be welded to tin or to sheet iron, but the stock will be discolored at the weld (p. 97)."
>
> "In welding brass, galvanized iron, tin, terne plate, German silver, aluminum, sherardized steel and all coated materials, it is advisable to use less pressure between the electrode points (p. 98)."
>
> "In welding tin, lead, or zinc-coated iron, both the upper and lower electrodes are pointed."

See also mention of tinned ware in agreement with Silesia Company, Rec., p. 433.

Mr. Gravell, plaintiff's expert, admitted the accuracy of these statements (Rec., p. 193, X-Q. 35).

Mr. McBerty has made and offered in evidence specimens of spot welding showing the practicability of spot welding tinned iron plates by both copper and steel electrodes (Rec., pp. 1014, 1015).

Extrusion of Metal

Realizing the straits in which it finds itself, plaintiff has endeavored, through its experts, to build up a theory of difference between the process or method involved in the welding of plane-faced plates and that involved in the welding of plates, like those of the Rietzel patent, in which one or both of the plates is or are provided with slight projections, founded upon what plaintiff is pleased to call the "extrusion of metal."

The theory has nothing substantial to support it. If there is extrusion of metal in one case, there is also in the other; but in any case it is negligible. The probabilities are that there is always and inevitably a slight extrusion of metal, if by extrusion we mean the lateral displacement of the metal at the point of fusion or welding under the pressure applied by the current-carrying pressure electrodes (Dyer, Rec., pp. 580, 586, 605).

Suppose we wish to weld a very thin metal plate provided at intervals with very small, short projections, or protuberances, to another metal plate having a practically plane face, as suggested by the Rietzel patent (Fig. 3). If, now, we lay these two plates together with the small projections or protuberances of one resting against the plane face of the other and then clamp them between two current carrying elec-

trodes with sufficient force to produce intimate pressure at the places of contact between the plates, and then turn on the current, it is clear that when the heat generated at the places of contact becomes sufficient to raise the temperature of the metal at those places to the fusing or welding point, the continued pressure of the electrodes will permit them to approach slightly nearer each other and, in so approaching, cause, possibly, a slight lateral displacement or flow of the softened metal of the plane-faced plate, on the one hand, and of the projections or protuberances of the counter-plate, on the other. This lateral displacement in the case of very thin plates having very low projections or protuberances will probably be immeasurably small and, in any case, entirely negligible.

When Mr. Townsend, plaintiff's counsel, was describing the disclosure of the Rietzel patent, he wrote (Rietzel patent No. 928,701, p. 1, line 92, Rec., p. 1099):

> "In carrying out my invention the *localization* of the flow of *heating electric current* and of welding *pressure* to the desired spot or spots may be brought about in any desired way. One of the preferred ways is by providing between the meeting surfaces or portions of the pieces to be united suitable conducting projections or points at the spots of union, which projections or points carrying the heating electric current from one piece to the other are so located in the meeting surfaces and are so separated from one another that on the application of the welding pressure *the welded union resulting* will be *localized in the area of the opposed surfaces* and will be *substantially co-extensive in area with the restricted area of the path of the effective heating current.*"

This, from plaintiff's own camp, seems to contradict the idea of there being any material extrusion of

metal. If the "welded union" is "localized on the area of the opposed surfaces" and "substantially coextensive in area with the restricted area of the path of the effective heating current," there can be substantially no extrusion.

Suppose, now, we wish to weld together two very thin plane-faced sheets or plates of metal by means of, say, a flat electrode on one side and a pointed electrode on the other. If, in such a case, we lay the overlapped sheets of metal between the electrodes and then cause the electrodes to approach one another, the plates will be pinched between the electrodes and the pointed electrode will, to a slight degree, bend or strike up the metal of the sheet against which it bears and, in effect, form a projection thereon (Dyer, Rec., p. 585), and if current is now turned on and maintained till the temperature of the parts of the plates that are thus brought into contact by the action of the electrodes reaches the fusing or welding point the softened metal will permit the electrodes to still further approach which will doubtless cause the softened metal to be slightly displaced or extruded, laterally—not to a degree that is of any moment, but, theoretically, somewhat.

Professor Thomson, who was swearing as hard as he could for the plaintiff company, of which he is vice-president and director, was obliged, reluctantly, to admit that in spot-welding there is "a *slight* movement of the metal" and that only "*practically all*" of the metal is included in the weld, as the following from his deposition shows (Rec., p. 535):

> "Q. 41. Are you prepared to say that there is no extrusion of metal at all, in the sense in which you have used that term in the making of a spot weld, so-called?

"A. There is a *slight movement* of the metal, but it is not manifested as an extrusion. The plates appear after the welding slightly indented or practically flat. The indentation, of course, means that the metal has *moved* but *practically all* of the metal is included in the weld, framed around by the unwelded material which being on edge opposes a very high force in the *spreading*." (Italics ours.)

By "manifested," Prof. Thomson may have meant "could not be seen," which, of course, would be usually true, as the welds are between the plates and out of sight.

Mr. Gravel, plaintiff's expert and general "stop gap" (having been put on the stand for the plaintiff five or six times), also found it necessary to step very lightly in regard to there being no displacement or extrusion in spot welding, so-called.

He testified on cross-examination, the first time he was produced, as follows (Rec., p. 85):

"X-Q. 118. Assuming that in spot welding the electrodes are placed firmly against the superimposed plates with no current on and that then, while the pressure continues to be applied, current is turned on and maintained until a proper welding of the plates has been effected, and that the current and pressure are then removed, will not the aggregate thickness of the plates at the point of pressure and welding be less after the completion of the weld than before?

"A. There is a slight depression at the weld which would make the aggregate thickness slightly less.

"X-Q. 119. I take it that very slight decrease in thickness is due to the heat and pressure involved in the welding operation. Is that not so?

"A. Yes.

"X-Q. 120. What has become of that displaced metal which the heat and pressure have displaced?

"A. Sometimes there is noticeable upset around the tool which has created the pressure. The amount of depression is usually so slight *that it is very difficult to say what becomes of the metal.* The condition is very similar to pressing any piece of metal with a blunt tool, either the metal must be upset or condensed.

"X-Q. 121. In ordinary spot welding is the metal softer at the contact point between the plates than it is at the point of contact between the electrodes and plates?

"A. In all probability while the metal is in the hot condition the greatest heat is at the center of the plane surface which is in the process of welding, because heat is continually flowing from this hot place to the surrounding metal, which is relatively cold. As the degree of softness is the function of the temperature, it naturally follows that the softest part of the metal would be located on the surfaces of the sheets between the sheets at the center of the heated spot.

"X-Q. 122. And if there is any flowage of metal, due to compression, it ought to take place in the greatest degree where it is softest, that is to say, at the proximate faces of the plates, ought it not?

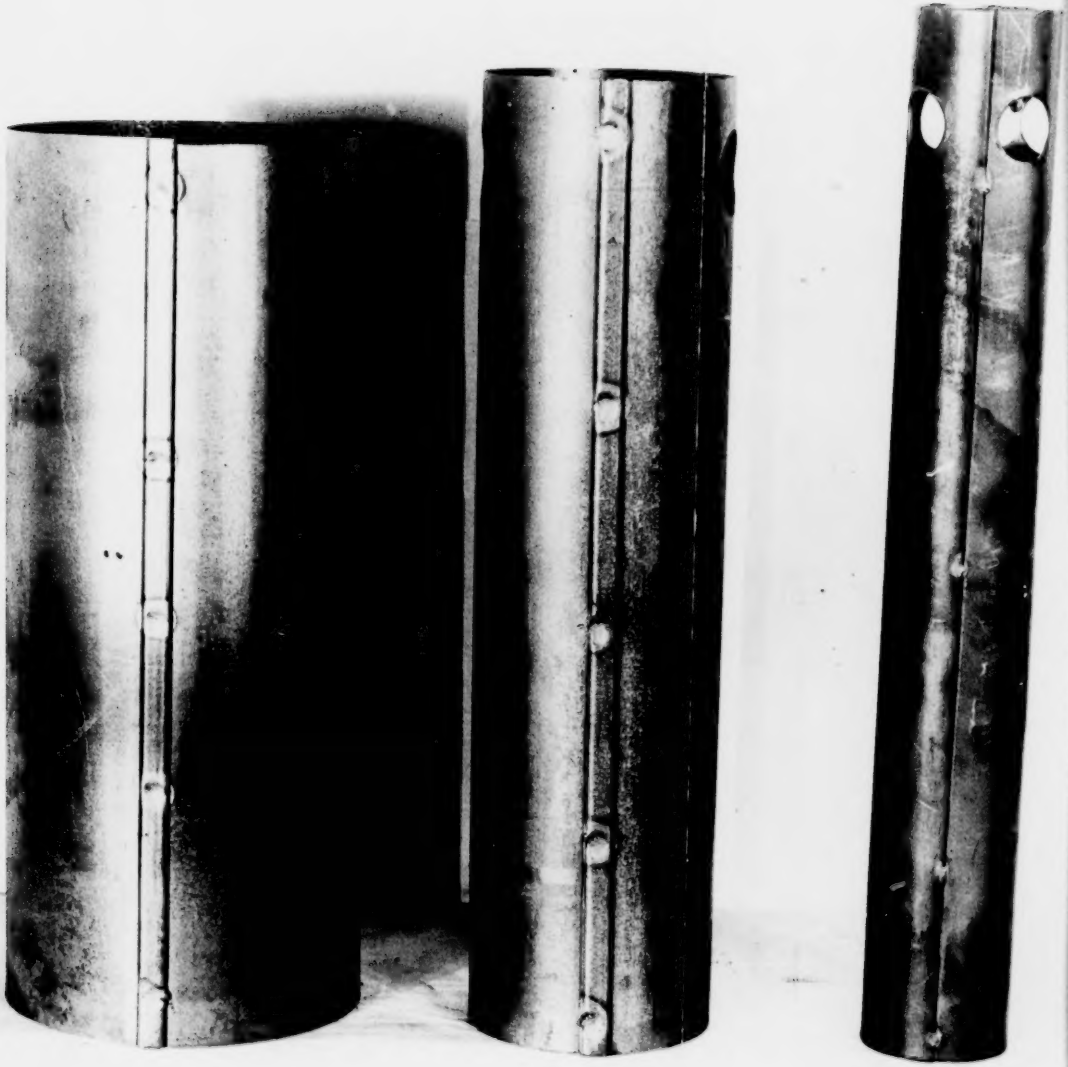
"A. This would be the case if the metal were not confined, but as the spot heated for welding is entirely surrounded by relatively cold metal, we can hardly think of the metal as flowing out or moving, except in so far as it is pressed strongly against itself, owing to the expansion due to the heating."

It is remarkable that a most careful examination of the original application of Harmatta fails to disclose any mention of the absence of extrusion of metal in the practice of his process or in any product or article that might result from the practice of his process.

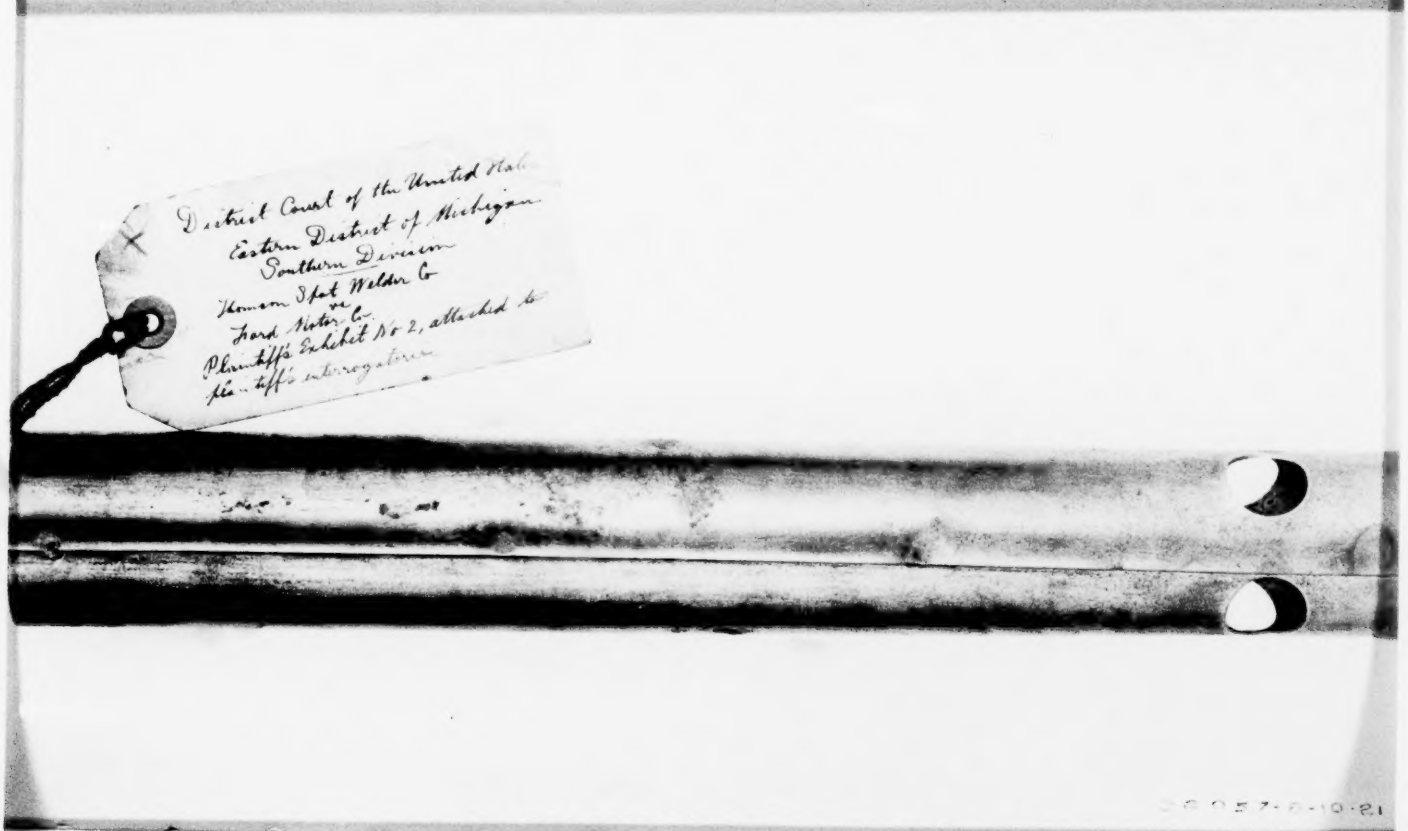
But it is more remarkable still, that in the Harmatta patent itself, the final draft of the specification and claims for which was prepared by Mr. Townsend—the Thompson Company's expert-of-experts in specification writing—there is not the slightest allusion to extrusion or the absence of it or to anything akin to it, either in the description of the process or in the description of the product.

It is, therefore, perfectly plain that the present exploitation of "the extrusion theory" represents a belated attempt on the part of the plaintiff to advance a point of differentiation which does not exist, and which, if it did exist, would be insubstantial and negligible.

What would it matter, we beg to inquire, if there were a slight extrusion or flowage of metal laterally from the place of welding of superposed sheets of metal, whether such sheets had projections or plane surfaces? In either case, the places of welding would be out of sight and there could be no possible disfigurement of the work nor impairment of the welds, and, in either case, the process of so-called spot welding would be produced.



None of the claims of the Harmatta patent refers to extrusion of metal or the lack of it, and each is broad enough to cover a process or method of operation which would be practiced whether or not extrusion occurred. The plaintiff must stand or fall by the claims as made, and can neither add anything to them nor subtract anything from them.



We repeat: The claims cover and were drawn to cover the welding of plates having pre-formed projections on one or both of them, such as disclosed by Rietzel, as well as the welding of plane-faced plates, and they are, therefore, anticipated and invalidated by the prior patents of Robinson, Kleinschmidt, de Ferranti and others.

If it is contended that any of them is limited to the welding of plates which have no projections on them, then that claim is anticipated and invalidated by the prior patents to Thomson, Lemp, Burton, Benardos and others, and is further invalidated on the ground that such a claim does not present a process or method that is substantially and patentably different from the process or method involved in the welding of plates provided with pre-formed projections.

The photograph opposite shows some of the practical applications of spot welding made at defendant's factory. It is a copy of Defendant's Exhibit No. 49, Dyer Photographs Sheet A-2, referred to by Mr. Dyer, in his testimony. (Rec., p. 584.) It will be noted that where the welds are made close to the edge of the lapped parts there is a slight lateral displacement or extrusion of the metal, but this does not affect the character of the weld nor involve any departure from the process employed to make it.

In this connection attention is called to the fact that in Plaintiff's Exhibit No. 2, attached to plaintiff's interrogatories, which is a spot welded muffler tube of defendant's manufacture and is claimed by plaintiff to support the charge of infringement, in this case, there are four welds indicated. (1) The first weld (next the perforations in the muffler) shows the impression of the pointed electrode about one-eighth of an inch from the edge of the overlapped top part and no extrusion of metal appears; (2) the second weld shows a slight extrusion of metal; (3) the third weld shows slightly more extrusion; and (4) the fourth weld shows much extrusion. A photograph of this plaintiff's Exhibit No. 2 is shown opposite.

District Court of the United Stat
Eastern District of Michigan
Southern Division
Homem Stat Welder Co
vs
Ford Motor Co
Plaintiff's Exhibit No 2, attached to
plaintiff's interrogatories

BECAUSE OF THE BREADTH AND INCLUSIVENESS OF THE HARMATTA PRODUCT OR ARTICLE CLAIMS THEY ARE ANTICIPATED AND INVALIDATED BY THE PRIOR PATENTS OF ROBINSON, KLEINSCHMIDT, BENARDOS AND OTHERS.

Interpreted as they must be, *in view of their origination in the Rietzel patent,* as covering and including products or articles formed from plates or parts one or both of which are provided with pre-formed projections, all of the product or article claims of the Harmatta patent must be held to be invalid in view of the prior patents to Robinson, Kleinschmidt, Benardos, and others.

The *Robinson Patent* No. 574,942, of January 12, 1897, not only shows and describes the welding of plates or parts, one of which has pre-formed separated welding projections, but, as we have seen, makes distinct claims for such subject-matter, as follows (Rec., p. 1074):

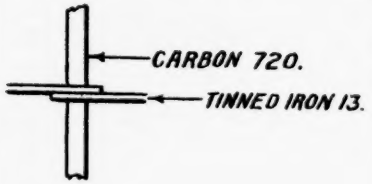
> "7. In a rail-joint, the truss or bottom plate B provided with the welding projections *d d*, with space between them, said projections being adapted to form several welding connections with the same rail, substantially as described.
>
> "8. In a rail-joint, a splice-bar constructed for welded attachment to one only of the abutting rails, said bar being provided with a plurality of welding projections grouped nearer to one end of said bar than the other, said projections forming a plurality of welding connections with the same rail, the portion of said splice-bar between said projections, and not raised to a welding heat, limiting the compression and regulating the predetermined relative position of said splice-bar and rail when welded together, substantially as described."

The characteristics of the Robinson structure set out in these quoted claims were urged by Prof. Thomson as peculiar to the Rietzel structure in an affidavit made by him and filed in support of the Rietzel application.

Prof. Thomson in that affidavit (verified November 30, 1908) said, among other things (Rec., p. 1784):

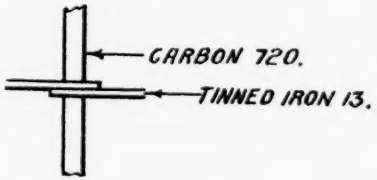
> "That in the invention of Mr. Rietzel aforesaid * * * the purpose is distinctly to limit the welding to a mere spot or spots, forming, in effect, a substitute union for that made heretofore, by perforating the plates at the spot or spots of union and then inserting a rivet and heading down said rivet."

Again (*Ibid*):



> "That in the Rietzel invention, in other words, the mechanical union of the plates is not over the whole area of the opposed or meeting surfaces, but at a number of isolated places which are, strictly speaking, spots, inasmuch as the welding portions of the plate form portions only of their meeting surfaces and are separated from one another over large areas by disunited portions, said disunited areas being anything desired consistent with the desired strength of the composite piece."

Again (*Ibid*, p. 1785):



> "The spot welding as contemplated by the Rietzel invention is entirely different in conception and application and affords a welding substitute for a riveted union. There is no welding over the areas between the spots at which the heating current starts and in fact there may be such a want of contact and union over such areas *as to allow a liquid to leak through between the plates*, etc."

EXPLANATION.

In this diagram, the illustrations in the upper line, reading from left to right represent, the first one in order, Fig. 7 of the Thomson patent 496,019, wherein the electrodes (carbon) are of relatively high resistance (720.) while the plates (tinned-iron) are of lower resistance (13.); the second, Fig. 2 of the Benardos German patent, wherein, also, the electrodes (carbon) are of relatively high resistance (720.) and the plates (assumed to be of tinned-iron) are of lower resistance (13.); the third, Fig. 2 of Benardos, wherein the electrodes (iridium) are of relatively low resistance (6.) and the plates (assumed to be of iron) are of higher resistance (8.85); the fourth, Fig. 2 of the Benardos patent, wherein the electrodes (iridium) are of relatively high resistance (6.) and the plates (assumed to be of copper) are of lower resistance (1.586); and the fifth, Fig. 4 of the Stanley patent, wherein the electrodes (tungsten) are of relatively high resistance (5.57) and the plates (copper) are of lower resistance (1.586).

The illustrations, in the second line, reading from the left represent, in order, first, Fig. 22 of the Thomson patent 436,019, wherein the electrodes (iron) are of relatively low resistance (8.85) and the plates (tinned-iron) are of higher resistance (13.); the second, Fig. 1 of the Harmatta French patent, wherein the electrodes (assumed to be of iron) are of relatively low resistance (8.85) and the plates (tinned-iron) are of higher resistance (13.); the third, the same Fig. 1 of the Harmatta French patent, wherein the electrodes (assumed this time to be of copper) are of relatively low resistance (1.586) and the plates (tinned-iron) are of higher resistance (13.).

The illustration on the third or bottom line represents the electrodes and plates of Fig. 1 of the Harmatta U. S. patent, concerning which no hint is given either as to the materials or resistances employed.

We might here observe that the Robinson patent under consideration was not cited during the prosecution of the Rietzel patent application. The fact that it was classified among "rail joints" would account for the fact that it was overlooked by the Examiner.

The *Kleinschmidt Patent,* No. 616,436, of December 20, 1898 (Rec., p. 1077), affords another complete anticipation of the product or article claims of Harmatta. Kleinschmidt, like Robinson, had for his object the welding of splice-bars to the webs of railroad rails. His splice-bars were generally plane-faced, but each had a relatively low projection near each end and a third low elongated projection extending across the face of the bar, at the middle.

To secure the splice bars to the webs of the rails the bars were first clamped to the webs, with their isolated projections against the latter, by means of electrodes, and the welding current was then turned on and maintained till the union was complete.

There were large areas of unwelded union between the welded projections.

This Kleinschmidt patent was likewise overlooked and not cited to Rietzel.

The prior *Benardos German Patent,* No. 50,909, of May 8, 1889 (Rec., p. 1148), affords another complete anticipation of the product or article claims.

In considering this Benardos patent, in its application to such product or article claims, it is, of course, immaterial by just what process or by what form of apparatus the Benardos product is produced, so long as the product, as such, is the same as Harmatta's.

If we take the apparatus of Fig. 2 of Benardos, place two overlapped metal plates between the electrodes, clamp the plates by means of the electrodes and turn on the current, as directed, the result will be the weld-

ing together of the plates at the spot or spots treated and the production of a product or article that answers the call of the Harmatta claims. And this will be true, whether the greater portion of the welding heat is generated at the contacting surfaces of the two plates, in the plates themselves, in the electrodes or in all of these places. This Benardos German patent was also not cited to Rietzel.

The product of the *Thomson Patent,* No. 396,015 (Rec., p. 1038), answers the terms of the Harmatta product claims for, in addition to the union of the plates by rivets, electrically set, the plates themselves are welded in spots.

The sixth claim of the patent makes this clear:

> "6. The herein described method of fastening two pieces of metal together, consisting in passing a heating current through a rivet or rivet blank passing through the pieces, *as well as through the pieces of metal themselves in the neighborhood of the rivet,* and applying pressure to set the rivet and weld the pieces together."

So, with the product of the *Thomson Patent,* No. 444,928 of January 20, 1891 (Rec., p. 1048), overlapped pieces to be welded when subjected to the action of the roller electrodes which apply both pressure and current, will inevitably be converted into a product falling within the terms of the Harmatta claims.

The Thomson patent says (p. 1, line 84):

> "The edges are slightly overlapped, as shown, and the plates, being in position between the rolls, may be squeezed together by means of the screw S, thus forming an electric contact between them. The electric current being now turned on as it passes from one roller to the other and across *the*

point of pressure will heat the work to the welding temperature and soften the same slightly, after which the screw may be driven a few more turns to effect a solid union.

"The work, *having been thus started,* may now be moved along through or between the rollers, *so as to bring successive parts of the joint* into position to be pressed and heated at the same time."

The *Lemp Patent,* No. 553,923 (Rec., p. 1067), affords another example of a product which falls within the terms of the Harmatta claims.

This patent is even a better reference than the Thomson patent last above considered, since, if there is anything material in the point, the roller electrodes of Lemp indubitably *do not,* in their position of operation upon the overlapped or superposed plates, extend way across the overlapped or superposed parts, *but only part way across.*

The *Thomson Patent,* No. 496,019 (Rec., p. 1055), which shows and describes the electrode welding of tin-coated iron plates, affords still another example of an anticipating product.

Other illustrations of products or articles answering the terms of the claims are found in the *Burton Patent,* No. 647,694 (Rec., p. 1079); the *Perry Patent,* No. 670,808 (Rec., p. 1083); the *Parkinson British Patent,* No. 14,836 of 1894 (Rec., p. 1112), and the *de Ferranti British Patent* of May 25, 1903 (Rec., p. 1122). The trial court and the Circuit Court of Appeals, in their written opinions, discussed with fullness the prior art patents above specifically referred to and concluded that they rob the Harmatta disclosures of both process and product of any patentably novelty (pp. 27-36, 2089).

BY THE CONDUCT OF PLAINTIFF'S PREDECESSOR IN TITLE, PLAINTIFF IS EQUITABLY ESTOPPED TO ASSERT HARMATTA'S PRIORITY OVER RIETZEL.

On the 24th day of February, 1905, Adolph F. Rietzel, of Lynn, Mass., then the superintendent, engineer and general manager of the Thomson Electric Welding Company, plaintiff's predecessor, for and in behalf of his company, made application for a United States Patent for what was characterized as "Improvements in Uniting the Component Parts of Composite Sheet-Metal Structures."

In this application, as originally filed, it was stated (Rec., p. 1723):

> "My invention relates to a method of forming an electrically welded union between the plane surface of a piece of metal and another piece of metal and is especially useful in uniting *two plates or sheets of metal at their plane surfaces.*
>
> "One of the special objects of the invention is to provide a method whereby a sheet of metal, especially in the thinner gages, may be united on its plane surface to another sheet or to any other piece of metal. For the sake of illustration, however, the process will be described as carried out in uniting two sheets or plates to one another, for which purpose the invention is particularly useful. It is to be understood, however, that I do not limit myself to the process as applied to sheet or plate metal or to uniting two plates or sheets with one another, since the invention is also applicable to forming a welded union with a plane surface or contact surface of considerable area in a piece of metal of any form.
>
> "It is not practicable by the present process of electric welding to weld together two plates or sheets of metal on their plane surfaces, on ac-

count of the large area of surface contact between them, when laid one upon the other, which allows the welding current to pass without bringing them up to a welding heat.

"My present invention consists essentially in providing over the surface to be welded a number of contact spots or points through which the welding current is passed in multiple and applying pressure in the proper way to form a number of distinct electric welds or spots of union over said surface.

"These contact spots act to localize the current and the heating to a welding temperature and may be provided either by casting, punching or indenting the metal of the plane surface with which the welded union is to be made, or otherwise forming the same so as to provide thereon a multiplicity of isolated projections, or said contact spots may be provided by disposing a number of small pieces of metal over said surface, which pieces become united with said surface and with the opposite piece or pieces of metal in the welding process."

In the drawings which accompanied and formed part of this Rietzel application there were shown several applications of the idea of welding in spots (Rec., p. 1827).

According to Fig. 1 a plate provided with a number of separated struck-up projections was to be united to a plane plate.

Fig. 2 showed two plates with struck-up projections that were adapted to be united at the projections.

Fig. 3 showed a plate with projections cast or formed wholly on its inner face in co-operation with a plane faced opposed plate.

Fig. 4 showed two co-operating plates provided with projections like those of the plate with projections in Fig. 3.

Fig. 5 showed two plane plates with interposed separate pieces of metal through which the welding was intended to take place.

In the application, as filed, there was no specific mention of the welding together of two perfectly flat plane plates in spots, *though, as we shall, later on, see, Rietzel had long before that time done work of that character at the Thomson Electric Welding Company's shops, at Lynn, Mass. When the application was filed Reitzel and his counsel evidently thought there was no novelty in such an application of resistance welding, or else that Reitzel's public use of it had barred his right to a patent.*

Perhaps the broadest claim that was presented with the application, as filed, was the eighth, which read as follows (Rec., p. 1728):

> "8. The herein described method of electrically welding a piece of metal at a plane surface thereof consisting in providing such plane surface with a current localizing projection, passing a heating current through such projection and applying pressure to unite said piece with another piece by a welded union coincident with such projection."

On June 8, 1908, the Primary Examiner, having already rejected the Reitzel application and an appeal to the Board of Examiners-in-Chief having been taken from such rejection, found a new anticipating reference, namely, British patent to Harmatta, No. 22,981 of 1903. In his letter to applicant, he said (Rec., p. 1760):

> "The Examiner proposes to direct the attention of the Board of Examiners-in-Chief to the British patent to Harmatta, 22,981 of 1903, Class

> 219, Welding (see Fig. 4 and lines 32 and 33, page 5), as additional ground for the rejection of claims 1, 3, 4 and 6. Fig. 4 of this patent shows a spot weld, which takes the place of a rivet, and it is not considered to be a patentable improvement to join two sheet metal plates by a number of such 'spot welds.' "

So far as this record shows this was the first time the British patent, or any patent, to Harmatta had been brought to the attention of Reitzel, or to the Thomson Electric Welding Company, his assignee. So straightway, to wit, on November 24, 1908 (Rec., p. 1762), the Rietzel application was amended and broadened so as to cover the Harmatta disclosure of electrically welding plane faced plates having no preformed projections upon them (Rec., p. 1130).*

This amendment took the form of a complete new specification and claims, the latter being expanded in number to twenty-three. The process of Rietzel was now no longer said to consist "*essentially* in providing over the surface to be welded a number of contact spots or points through which the welding current is passed in multiple," as in the original, but was characterized thus (Rec., 1762):

> "Briefly stated, the invention consists in electrically welding pieces together in a spot or spots definitely located in and involving a portion only of their meeting surfaces as hereinafter more particularly described and claimed."

And the product of the Rietzel process was characterized thus (*Ibid.*, p. 1763):

*See Townsend testimony, Rec., p. 622, et seq.

"A weld formed according to my invention is distinguished, however, from such prior welds by the fact that a portion only of the opposed surfaces is welded together, such portions being coincident with and limited to spots in the areas of such opposed surfaces in which spots the heating electric current is localized or confined in any desired way so that the major portion of the opposed surfaces will not be involved in the welding, although they may, after the completion of the operation, lie in contact with one another or very close together."

Of the twenty-three new claims presented the following are typical (*Ibid.*, p. 1769):

"1. The hereinbefore described improved method of fastening two pieces of metal together by electrically welding them to one another at a spot or spots only of their juxtaposed or opposite faces.

"2. The herein described method of uniting two pieces of metal at a number of distinct or separate spots separated from one another by well-defined areas of no union, consisting in applying pressure localized at the spots of desired union, passing electric current through the pieces from one to the other, and confining the flow of current to said spots until the union is effected.

* * * * *

"6. The method of uniting sheets of metal by pressing them together and at the same time passing a heating and welding current from one to the other at a spot on their meeting surfaces which is restricted in area throughout the operation so as to leave on the meeting surfaces a well-defined and comparatively extensive area of no union completely surrounding said spot.

* * * * *

"16. Composite metal work, having its component pieces welded together at one or more spots

localized on their meeting surfaces or portions so as to be separated from one another on said meeting portions by distinct areas which are unwelded.

"17. Metal plates fastened together at their meeting portions by a number of distinct or isolated welds formed at spots of such restricted area and so separated from one another that when welding electric current is passed from one to the other at said spots, the metal between the spots will not be brought to plastic or welding condition."

It can not be doubted that this new amended description and these new amended claims were aimed specifically at, and intended to include, cover and subordinate, the disclosure of the Harmatta British patent. The attorney who did the work—Mr. H. C. Townsend, of New York—was a pastmaster at patent drafting, was thoroughly skilled in the art of electric resistance-welding and was, in fact, the one who drew the original Thomson "Art" patent. But something had to be done to get rid of the Harmatta British patent as an anticipation of Rietzel, and to establish Rietzel's priority over Harmatta.

Rule 75 of the Patent Office provides as follows:

"75. When an original or reissue application is rejected on reference to an expired or unexpired domestic patent which substantially shows or describes but does not claim the rejected invention or on reference to a foreign patent or to a printed publication, and the applicant shall make oath to facts showing a completion of the invention in this country before the filing of the application on which the domestic patent issued, or before the date of the foreign patent, or before the date of the printed publication, and shall also make oath that he does not know and does not believe that

> the invention has been in public use or on sale in this country, or patented or described in a printed publication in this or any foreign country for more than two years prior to his application, and that he has never abandoned the invention, then the patent or publication cited shall not bar the grant of a patent to the applicant, unless the date of such patent or printed publication be more than two years prior to the date on which application was filed in this country."

Now, it so happened that while the Provisional Specification of the Harmatta British patent was filed October 23, 1903 (Rec., p. 1124), the Complete Specification was not filed till July 25, 1904, not accepted till August 25, 1904, and not sealed till November 8, 1904.

The patent, therefore, really did not count, *as a patent*, under British law, till November 8, 1904, the day of sealing of the Complete Specification.

In order, therefore, to successsfully "swear back of" the Harmatta patent, it was necessary that Rietzel should "make oath to facts showing a completion of the invention in this country" * * * before the effective date of that patent, that is to say, before its date of sealing.

Such an affidavit or "oath to facts" was immediately prepared by Mr. Townsend and executed by Mr. Rietzel and filed, with the following statement (Rec., p. 1775):

> "We submit herewith substitute specification and claims in the above-entitled case, together with an affidavit of the inventor, making oath to facts showing a completion of the invention in this country before the legal date of the foreign patent to Harmatta, cited by the Examiner as an anticipating patent."

The affidavit of Rietzel referred to was as follows (Rec., p. 1778):

"County of New York, State of New York, ss.:

"ADOLPH F. RIETZEL, being duly sworn, deposes and says that he is the applicant who filed the above entitled application for patent; that some time in June, 1904, he successfully practiced the invention in said application by uniting two halves of a sheet metal pulley in an electric welding machine at the shop of the Thomson Electric Welding Co., in Lynn, Mass.; that the piece of sheet metal herewith attached and marked 'Specimen of pulley C. F. Tischner, Jr., * * * N. P.,' is a duplicate of one of the halves of the pulley to which he at that time applied the invention; that the contact points or projections formed in the sheet metal were in the first instance made by filing the metal to leave the contact points or projections, indenting not being available at that time, but that in subsequent operations in which his invention was employed the projections were made by indenting the sheet metal, and that the invention was frequently practiced by him successfully at the shop of said company on a standard welding machine; that in conducting the operations on such machines he employed a pair of contacts fitted in the jaws of the machine and formed at their outer ends so as to fit into the cup shaped portion of the halves of the sheet metal pulley to be welded, thereby supporting the two halves with the contact projections engaged with one another; the two halves being in contact by the projections while assembled in the machine, electric current was caused to pass through the two halves by the contact projections, and pressure was then applied in the usual way practiced in electric welding by the standard machine in which the operation in question was conducted; the operations above recited as conducted by him were uniformly

successful and demonstrated clearly that the invention was complete in all particulars, and that the said invention has been since practiced on innumerable occasions in substantially the same way for uniting pieces of sheet metal such as the halves of sheet metal pulleys of the form shown in the exhibit and of other forms and of other sizes, many of much larger size than that of the exhibit; that he does not know and does not believe that the invention aforesaid has been in public use or on sale in this country, patented or described in a printed publication in this or any foreign country for more than two years prior to his application and that he has never abandoned the invention.

ADOLPH F. REITZEL.

"Subscribed and sworn to by the aforesaid Adolph F. Reitzel before me this 23d day of October, 1908.

C. G. TISCHENER, JR.,
"(Seal) *Notary Public.*
"Notary Public, Kings County.
"Certificate filed in New York County."

Accompanying the amendment to the Rietzel specification and the affidavit of Rietzel referred to was a supporting affidavit of Prof. Elihu Thomson, as to the value of Rietzel's improvement. In this affidavit Prof. Thomson said (Rec., p. 1782):

"That he is familiar with the process of electric welding set forth in the above entitled application of A. F. Rietzel for uniting sheets of metal together by what has been known as the 'spot welding process' and which forms a practical substitute for the riveting of plates together or for other mechanical expedient for fastening them together face to face;"

Again, contrasting the Rietzel improvement with a prior invention of one Hunter, Prof. Thomson said (*Ibid.*, p. 1784):

> "That in the invention of Mr. Rietzel aforesaid, the object and essential operation are entirely different from that of the Hunter process or invention, for the reason that there is no purpose in the Reitzel invention of forming a lap weld continuous over the whole opposed surfaces of the sheet metal pieces, but on the contrary the purpose is distinctly to limit the welding to a mere spot or spots, forming, in effect, a substitute union for that made heretofore, by perforating the plates at the spot or spots of union and then inserting a rivet and heading down said rivet."

Again, referring to the exhibit filed with Mr. Rietzel's affidavit, Prof. Thomson said (*Ibid.*, p. 1786):

> "The accompanying exhibit marked 'Rietzel Exhibit No. 3, J. A. McManus, N. P.,' and also with my initials 'E. T.,' is a specimen of a lap welding made by forming initial projections at such distances apart that *cold metal* will be left between said projections and the union will be, therefore, by a line of separate welded points, etc."

On Dec. 14, 1908, the broad claim 1 introduced by the amendment of Nov. 30, 1908, and which read as follows (*Ibid.*, p. 1769):

> "1. The hereinbefore described improved method of fastening two pieces of metal together by electrically welding them to one another at a spot or spots only of their juxtaposed or opposite faces";

was rejected on the French patents to Egel, Nos. 356,187 and 335,889.

Claim 2, also, then standing in the case, read as follows (Rec., p. 1769):

"2. The herein described method of uniting two pieces of metal at a number of distinct or separate spots, separated from one another by well defined areas of no union, consisting in applying pressure localized at the spots of desired union, passing electric current through the pieces from one to the other and confining the flow of current to said spots until the union is effected."

Regarding this claim the Commissioner in his letter of rejection said (*Ibid.*, p. 1788):

"Claim 2 is objectionable because the expression, 'Confining the flow of current to said spots,' *implies the use of apparatus such as a pointed electrode.* The claim is, therefore, misleading as applied to the method described by applicant. A similar objection is made to the expression, 'Localizing the pressure in and confining the flow of current' in claim 4; 'localizing the heating current' in claim 7; 'Confining the welding area of such current' in claim 8, and 'Confining the area of heating' in claim 14.

"Claims 2 to 7, inclusive, are rejected on either of the French patents cited above."

These French patents were founded on a communication from Harmatta himself, Patent No. 336,187, being a substantial copy of the Harmatta application as originally filed in this country and in Great Britain. Compare drawings of Egel (Rec., p. 1143), and translation of specifications, (*Ibid.*, p. 1144), with original U. S. Harmatta application (Rec., p. 1156, *et seq.*,) and Harmatta British patent, (Rec., p. 1124).

That a disclosure of these French patents did, in fact, emanate from Harmatta is shown by Harmatta's oath appended to his U. S. application, in which he so states (Rec., p. 1364), and by Harmatta's oaths to

three preliminary statements that he subsequently filed in interference cases in which his U. S. application was involved (Rec., p. 1846; *Ibid.*, p. 1914; Rec., p. 1473).

On March 13, 1909, Rietzel struck out his amended claim 1, last above quoted, and filed a substitute for it, reading as follows (Rec., p. 1796):

> "1. The hereinbefore described improved method of fastening two pieces of metal together by electrically welding them to one another at spots only of their juxtaposed or opposite faces by the application of pressure and heating current localized in such spots."

At the same time, the specification was further amended by the addition of the following paragraphs, among others (*Ibid.*, p. 1795):

> "Briefly stated, the invention consists in electrically welding pieces together in spots definitely located in and involving a portion only of their meeting surfaces, by the application of pressure and heating current localized in such spot or spots."

Again (*Ibid.*, p. 1796):

> "A weld formed according to my invention is distinguished, however, from such prior welds by the fact that the opposed surfaces are welded together in spots only, the heating electric current being localized or confined in any desired way to such spots so that the major portion of the opposed surfaces will not be involved in the welding, although they may, after the completion of the operation, lie in contact with one another or very close together."

With this new amendment was filed another antedating affidavit from Rietzel, under Rule 75, for the purpose of justifying the claiming by him of the process when worked out by the use of a pointed electrode and of "short-circuiting" the French patents which disclosed the use of such pointed electrodes the attorney's letter of transmittal stating (*Ibid.*, p. 1800):

> "We file herewith an affidavit establishing completion of the invention on applicant's part prior to the dates of the French patents cited by the examiner in his last official letter."

It is interesting to note, at this point, that the first oath filed by Rietzel, under Rule 75, for the purpose of overcoming the effect of the British patent, only undertook to carry his date of invention back to "sometime in June, 1904," and referred to the successful completion and reduction to practice at that time of that embodiment of his spot welding invention which consisted in the welding together of plates having pre-formed projections through which the welding in spots took place.

That first affidavit was, therefore, insufficient to meet the case of the later cited French patents because the work of Rietzel set out in such first affidavit was alleged to have been done in June, 1904, whereas, the first of the French patents was published on *February* 18, 1904 (Rec., p. 1136), or four months earlier; and, further, because Rietzel apparently could not truthfully say he had successfully worked out his method of welding through projections before June, 1904.

When we come, therefore, to examine the second Rietzel affidavit, we find that in it Rietzel swore that

prior to the 18th day of February, 1904 (but how long prior he did not state nor have to state), he had successfully and repeatedly welded together sheets of metal face to face, *by the use of a pointed current-carrying electrode applied to one side of the superposed plates and a flat electrode applied to the other side;* or, in other words, he swore to the successful practice by *him* of the identical application of the electric resistance process of welding together plane-faced metal plates by means of a pointed electrode disclosed in the Harmatta British and French patents, *prior* to the effective dates of those patents.

The second Rietzel affidavit, in full, is as follows (Rec., p. 1791):

> "County of New York, State of New York, ss.
>
> ADOLPH F. RIETZEL, being duly sworn, deposes and says, that he is the applicant that filed the above entitled application for patent;
>
> That prior to the 18th day of February, 1904, he repeatedly successfully practiced the method of fastening two sheets of metal together face to face by welding them at spots in their meeting surfaces by confining the heating electric current passed from one plate to the other in such spots and localizing the welding pressure at said spots, as claimed broadly in said application;
>
> That the work of so uniting such sheets of metal was done at the factory of the Thomson Electric Welding Company at Lynn, Massachusetts, on a welding machine of a commercial type known as type 10 A Welder;
>
> That said machine was the same in construction as the machine known as type 5 A Welder, but of larger size, and was identical with that shown on the attached page removed from a catalogue of the Thomson Electric Welding Company, which page is identified and marked 'Page of Catalogue, D. M. Edsall, N. P.';

That the accompanying pieces of work marked 'Specimen No. 1, D. M. Edsall, N. P.' and 'Specimen No. 2, D. M. Edsall, N. P.,' are duplicates of work so done by him on that machine prior to the 18th day of February, 1904, but that the original specimens were not preserved;

That in doing such work he employed a pointed electrode, the same in form as the accompanying electrode marked for identification 'Welding Electrode, D. M. Edsall, N. P.,' which electrode was clamped in one of the holders of the machine and was used to apply the localized pressure and heating current to the plates which were welded together at spots in their superficial area, the opposite or backing electrode being a block of metal which was flat and of a superficial area, approximating the area of the plates which were welded together and which opposite electrode was clamped in the opposite holder of the machine;*

That in this operation the two plates superposed upon one another were inserted between said electrode and the pressure and heating current localized as claimed were applied by forcing the pointed electrode against the outside face of the plates and pressing them between said pointed electrode and the opposite flat electrode, current being at the same time passed from one electrode to the other and pressure being applied by employing the usual devices forming a part of the machine and used in the ordinary operation of the machine for applying welding pressure to the work;

That the work was repeatedly and successfully done in this manner upon various sizes and pieces of metal plates, none of which, however, are now in existence so far as affiant has been able to discover;

---

*The specimen of work and the welding electrode filed with this affidavit have been diligently searched for at the Patent Office but cannot be found. (See Friess, Rec., p. 708.)

That the work done by him aforesaid, demonstrated the complete success of the operation and that metal plates could be successfully and firmly united together by distinct or isolated electric welds forming welded spots of union in their meeting faces and constituting in effect a successful substitute for a union of the same by a number of rivets.

ADOLPH F. RIETZEL.

Subscribed and sworn to before me this 18th day of February, 1909.

DAVID M. EDSALL,
(Seal) *Notary Public, N. Y. Co.*"

The Harmatta British and French patents having been thus disposed of as references, the attorney for the Thomson Company proceeded further to broaden the Rietzel application by inserting the following in the specification (*Ibid.*, p. 1806):

"The product in the form of sheet metal is further particularly useful for sheet metal ware since the outer or exposed surface of the metal will have the smooth and practically unaltered finish of sheet metal and said surface will not be substantially marred when the process is properly conducted, excepting for the presence of such infrequent small depressions as might remain from the previous indentation of the metal from the back when, as hereinbefore described, an indenting of the metal may be resorted to.

"The product in sheet metal also possesses the advantage that the spots of welding when located within the edges of the meeting surfaces will not show. The product is also superior to that produced by riveting of the plates in that there are no rivet heads to mar the finish of the back or outer surfaces of the metal."

Also, by adding the following product or article claims (*Ibid.*, p. 1807):

> "17. Sheet metal work comprising pieces of sheet metal welded together in the material of their meeting surfaces and in spots only, each surrounded by distinct areas of unwelded union, the back surfaces of said pieces being substantially unaltered over the welded spots, substantially as and for the purpose described.
>
> 18. Composite metal work having its component pieces welded together in spots only involving the material of their opposed or meeting surfaces, said spots being each entirely surrounded by distinct areas of unwelded union and the portion of the pieces back of the welds being substantially unaltered, as and for the purpose described.
>
> 19. Metal work comprising a metal plate fastened on its surface to the opposed surface of another piece of metal by a weld at a spot only in the material of the opposed surfaces, said spot being surrounded by a distinct area of unwelded union and the back surface of said plate being practically unaltered over said spot, as and for the purpose described."

Later, on June 19, 1909, another product or article claim was added, reading as follows (*Ibid.*, p. 1814):

> "20. A metal article comprising two bodies of metal having adjacent plane surfaces united at a plurality of spaced and isolated spots of integral and autogenous welded union, the metal at the spots of welded union having substantially the same qualities as at other points."

And then, on July 20, 1909, having been drawn by a master hand with reference to the early work of Rietzel in the electrode-welding of plane-faced plates, to Riet-

zel's later work in the welding of plates with projections, to the disclosures of Harmatta British and French patents, and to the practical up-to-date development of the art of so-called "spot welding,"* the Rietzel patent with twenty claims,—sixteen to process and four to product—was issued to the Thomson Company, as the assignee of Rietzel, and the whole practical art of "spot welding" was supposed thereby to have been delivered into the hands of the Thomson Company and left there completely at the latter's mercy!

But a curious and unexpected thing then happened. On April 14, 1910, like a bolt from a clear sky, came notice from the Patent Office to the Thomson Company that the issued Rietzel patent had been put in interference with a pending United States application of Harmatta, both as to process and product claims (Rec., p. 1819) and both parties were called upon to file their preliminary statements.

These preliminary statements, in interference proceedings, are in the nature of sworn pleadings, are strictly binding upon the parties and very difficult, indeed, of amendment.

In consequence, great care is required in their preparation.

The Patent Office rule regulating the matter is Rule 110, which reads as follows:

> "110. Each party to the interference will be required to file a concise preliminary statement, under oath, on or before a date to be fixed by the office, showing the following facts:

*Spot welding machines for the welding of plane-faced metal plates, face to face, were on the market in this country as early as 1906-8 (McBerty, Rec., p. 742; Taylor, Rec., p. 898; Rietzel, Rec., p. 638; Clark, Rec., p. 261).

(a) The date of original conception of the invention set forth in the declaration of interference.

(b) The date upon which the first drawing of the invention and the date upon which the first written description of the invention were made.

(c) The date upon which the invention was first disclosed to others.

(d) The date of the reduction to practice of the invention.

(e) A statement showing the extent of use of the invention.

(f) The applicant shall state the date and number of any application for the same invention filed within twelve months before the filing date in the United States, in any foreign country adhering to the International Convention for the Protection of Industrial Property or having similar treaty relations with the United States.

If a drawing has not been made, or if a written description of the invention has not been made, or if the invention has not been reduced to practice or disclosed to others or used to any extent, the statement must specifically disclose those facts.

When the invention was made abroad, the statement should set forth:

(a) That the applicant made the invention set forth in the declaration of interference.

(b) Whether or not the invention was ever patented; if so, when and where, giving the date and number of each patent, date of publication, and the date of sealing thereof.

(c) Whether or not the invention was ever described in a printed publication; if so, when and where, giving the title, place, and date of such publication.

(d) When the invention was introduced into this country, giving the circumstances with the dates connected therewith which are relied upon to establish the fact.

The preliminary statements should be carefully prepared, as the parties will be strictly held in their proofs to the dates set up therein.

If a party prove any date earlier than alleged in his preliminary statement such proof will be held to establish the date alleged and none other.

The statement must be sealed up before filing (to be opened only by the examiner of interferences; see Rule 111)*, and the name of the party filing it, the title of the case, and the subject of the invention indicated on the envelope. The envelope should contain nothing but this statement."

Now, the call of the sworn preliminary statement was quite different from the call of the affidavit under Rule 75, because, whereas, the affidavit under Rule 75 only required that the applicant should swear to facts showing a completion of the invention *prior* to the date of the patents set up in anticipation, the preliminary statement required that the *actual dates* respecting the conception and development of the invention should be set forth, with particularity. The Thomson Company, guided as it was by astute counsel, knew perfectly well that Harmatta's date of invention was as early at least as the date of the application for his British patent, i. e., October 23, 1903, since that patent had been formerly cited against Rietzel's application as an anticipation thereof and as a bar thereto; and it also knew that, under the International Convention (25 Sta. at L., 1383), and Section 4887 R. S. U. S., Harmatta could claim the benefit of his foreign filing date as the effective filing date of his application in this country, the Statute providing that:

*A similar statement repeating these declarations was later, to-wit, on Sept. 14, 1911, filed by Rietzel to cover a number of additional issues or counts added to the interference (Rec., p. 1917).

> "Sec. 4887. An application for patent for an invention or discovery or for a design filed in this country by any person who has previously regularly filed an application for a patent for the same invention, discovery or design in a foreign country which, by treaty, convention, or law, affords similar privilege to citizens of the United States, shall have the same force and effect as the same application would have if filed in this country on the date on which the application for patent for the same invention, discovery, or design was first filed in such foreign country."

And the Thomson Company further knew, and this is most important, that if it did not set up for Rietzel a date of invention earlier than October 23, 1903, a judgment on the record would straightway be entered in favor of Harmatta and against Rietzel by virtue of Patent Office Rule 114, which reads as follows:

> "114. If the junior party to an interference, or if any party thereto other than the senior party fail to file a statement, or if his statement fail to overcome the *prima facie* case made by the respective dates of application, such party shall be notified by the Examiner of Interferences that judgment upon the record will be rendered against him at the expiration of thirty days, unless cause be shown why such action should not be taken. Within this period any of the motions permitted by the rules may be brought. Motions brought after judgment on the record has been entered will not be entertained unless sufficient reasons appear for the delay."

Accordingly, to enable the Thomson Company to avert an immediate judgment against it, to obtain a "look-in," so to speak, in the interference, and to en-

able it to contest, at all, the question of priority of invention as between Rietzel and Harmatta, it caused to be prepared and sworn to by Rietzel a preliminary statement in which Rietzel declared (Rec., p. 1863)—

> "That he conceived the invention set forth in the declaration of interference during the latter part of October or first part of November, 1897; That, as near as deponent can at this time fix the date, the invention was successfully reduced to practice in the latter part of July, 1898, and at the same time was first explained and disclosed to others."

With the status thus acquired by the filing of this sworn preliminary statement, the Thomson Company proceeded, very leisurely, to occupy itself, not with the taking and submission of proofs as to Rietzel's electric welding operations in 1897-1898, but with the bringing of numerous technical motions to dissolve and the prosecution of many appeals challenging the patentability of the issues to Harmatta in view of certain admissions and disclaimers he was alleged to have made in the course of amendments to his application (Rec., pp. 1852, 1853), and challenging also the right of Harmatta to contest the interference because of the insufficiency of his oath to inventorship of the subject-matter of the issues (*Ibid.*, p. 1853), etc., etc.; the times for taking testimony in behalf of Rietzel being meanwhile extended, from time to time, under one pretext or another, so as to preserve that right.

On the 3rd day of February, 1902, nearly two years after the institution of the interference, the Thomson Company, through one of its counsel, Mr. Thatcher (a partner of Mr. Townsend), went abroad and procured from Harmatta an assignment of his pending appli-

cation (Rec., p. 1949), which, of course, gave the Thomson Company control of *both sides* of the interference, though, in form, Messrs. Townsend & Decker still appeared on the record as attorneys for Rietzel, and O. E. Duffy & Son as attorneys for Harmatta.

On May 10, 1912, these attorneys for the Thomson Company entered into a solemn stipulation again extending Rietzel's time for taking testimony (*Ibid.*, p. 1940), which was favorably acted upon by the Examiner of Interferences on May 13, 1912 (*Ibid.*, p. 1941), and Rietzel given until July 11, 1912, to take his testimony.

On July 15, 1912, no testimony having been offered in behalf of Rietzel, O. E. Duffy & Son made a solemn motion for judgment in favor of Harmatta because of the default of Rietzel to take testimony, which motion was duly and formally served on Townsend & Decker, attorney for Rietzel, and on July 24, 1912, the Examiner of Interferences entered an order to the effect that unless Rietzel should on or before August 3, 1912, show cause to the contrary, judgment would be entered against him (*Ibid.*, p. 1943); and, on the day last named, no cause having, of course, been shown, judgment of priority was entered against Rietzel and in favor of Harmatta and a limit of appeal fixed, as of August 27, 1912 (*Ibid.*, p. 1945).

It is interesting to note that Rule 125 of the Patent Office provides as follows:

> "125. After the interference is finally declared, it will not, except as herein otherwise provided, be determined without judgment of priority founded either upon the testimony, or upon a written concession of priority by one of the parties, signed by the inventor himself (and by the

assignee, if any), or upon a written declaration of abandonment of the invention."

The Thomson Company, being in control of the whole situation, doubtless figured that to offer testimony for Rietzel, or to file a concession of priority by him, or to file a declaration of abandonment by him might involve the relinquishment of some right. It wished to hold on to all that Rietzel had asserted to be his and at the same time secure new and further protection, for the same thing, through Harmatta.

So it simply suffered a judgment by default to go against Rietzel. It then proceeded to hold on to the Rietzel patent, with all its twenty (20) claims till *June 12, 1915*, nearly three years later, when it filed a disclaimer as to some of the claims.

Rietzel, himself, was kept in ignorance as to how the interference was being manipulated. He testified he was not advised as to the outcome of the interference, that he did not know judgment of priority had been entered in favor of Harmatta, nor, till put on the stand in this case, that a patent had been issued to Harmatta (Rec., p. 651, Q. 123, *et seq.*).

After the judgment in favor of Harmatta in the interference case became final, the Harmatta specification and claims were again rewritten and the patent was, on December 3, 1912, *just nine years, to a day*, after the application for it was filed, granted and issued to Thomson Electric Welding Company, as the assignee.

While, as we have seen, the Harmatta application was in adversary hands, and while the sworn representations made in the Rietzel preliminary statements that Rietzel was the prior inventor over Harmatta were staving off a judgment on the record against Riet-

zel and giving to the Thomson Company the potential right to contest priority with Harmatta, the Thomson Company was developing a licensing system under the Rietzel patent from which it was deriving profit by way of royalties from users of spot welding machines that electrically welded plane-faced plates; (Rec., p. 2019) was notifying and suing users of spot welding machines for welding plane-faced plates that such use was an infringement of that patent; was suing for infringement of that patent users of even what are alleged to be Harmatta spot welding machines (Rec., p. 1991; Rec., p. 227); and was, in fine, asserting the Rietzel patent to be a good, all-covering patent for all that it claimed.

The grounds upon which defendant bases its defense of equitable estoppel may, therefore, be summarized as follows:

(1) In the matter of the granting and issuing of patents the Commissioner stands as the agent and representative of the public at large.

(2) The plaintiff's predecessor in title, Thomson Electric Welding Company, when soliciting the grant of the Rietzel patent, represented to the Commissioner of Patents, through the affidavits of Rietzel filed under Rule 75, to its own advantage and to the prejudice of the public, that Rietzel had invented both the process of electrically welding plane faced metal plates as well as the process of electrically welding metal plates provided with pre-formed projections, and the products of those processes, *before* the dates of the Harmatta British and French patents; and, on the strength of such representations, and on that alone, the Commissioner granted the Rietzel patent, with claims including and covering the disclosure of Harmatta, and, so-called "spot welding," generally.

(3) When the Rietzel patent was subsequently put in interference with Harmatta's United States application plaintiff's predecessor in title, Thomson Electric Welding Company, through the two sworn preliminary statements of Rietzel filed by it on the 20th of June, 1910, and on the 14th of September, 1911, respectively, represented to the Commissioner the reduction to practice by Rietzel of the inventions of the processes and products involved in the interference as early as 1898 and the further assertion of the priority of Rietzel over Harmatta in respect of said processes and products, thereby, to its own gain and advantage and to the prejudice of the public, averting an immediate judgment of priority against the Rietzel patent,* giving the Thomson Company a "look-in" in the interference, and enabling it, through Rietzel, to contest priority with Harmatta, and also enabling it to employ the already granted Rietzel patent for a period of nearly three years and a half before the issue of the Harmatta patent (and for three years afterward and till a disclaimer was filed) as a title upon which to found a licensing system and under which to threaten and to sue users of electric spot welding machines, including even users of so-called Harmatta machines, for the welding of plane-faced plates.

(4) The truth or falsity of the representations made by the plaintiff's predecessor to the Commissioner has nothing to do with the efficacy of the estoppel urged. It is the *fact* of the representations, not their truth, and the *fact* that the Commissioner acted upon the representations to the prejudice of the pub-

*It is enough if a party has been induced to *refrain* from using such means, or taking such action, as lay in his power by which he might have retrieved his position and save himself from loss. *Pomeroy's Eq. Jur.*, Vol. II, p. 1444.

lic, first, by the granting and issuing of the Rietzel patent and thereby imposing upon the public a patent that would, otherwise, not have been granted; and secondly, by the withholding of judgment against Rietzel in the interference for a period of nearly three and a half years—which judgment would otherwise have been rendered at once—that present the essential elements of an equitable estoppel.

It is immaterial whether Rietzel did or did not, in 1898, before Harmatta entered the field, "successfully reduce to practice" the process of electric welding or the product of such process covered by the issues in the Rietzel-Harmatta interference (Rec., p. 1838; *Ibid.*, p. 1907) and by the claims of the Harmatta patent here in suit. The Thomson Electric Welding Company so represented the fact to be to the Commissioner of Patents in the affidavits under Rule 75, and in the two Rietzel sworn preliminary statements, and, now, when the plaintiff asserts the Harmatta patent against the defendant, and the defendant confronts it with the former solemn sworn representations of its predecessor in title declaring Rietzel's prior inventorship, it is manifestly unjust and inequitable that it be heard in this Court of Equity to deny that Rietzel was prior.

It is blowing hot and cold, with a vengeance, to assert at one time, when it serves its purpose, that Rietzel is the prior inventor over Harmatta, and to assert, at a later period, when its interest is different, that Harmatta is prior.

(5) The plaintiff having, by assignment, derived its title to both the Rietzel patent and the Harmatta patent from the Thomson Electric Welding Company (Rec., p. 1968), is, through its privity with that com-

pany, bound and estopped by the acts and representations of the latter.

(6) The defendant, as member of the general public, is entitled to urge the estoppel growing out of the acts and representations aforesaid made by plaintiff's predecessor in title to the Commissioner and upon which the Commissioner, as the representative of the general public, acted, as aforesaid, to the prejudice of the public and of the defendant as a member thereof; and especially is this so as against any demand of the plaintiff asserted under the Harmatta patent, since defendant began and was established in the practice of spot welding of plane-faced metal plates in 1911 and 1912 before the Harmatta patent issued (Smith, Rec., p. 1004; Wibel, *Ibid.*, p. 1002; Prosser, *Ibid.*, p. 997; Findlater, *Ibid.*, p. 995; Evely, *Ibid.*, p. 992; Mills, *Ibid.*, p. 990; Wright, *Ibid.*, p. 987; Neeland, *Ibid.*, p. 985).

The Law of Equitable Estoppel

In Pomeroy's Equity Jurisprudence we find the following careful statement of the essential elements constituting estoppel (Vol. II, p. 1423, par. 805):

> "1. There must be conduct—acts, language, or silence—amounting to a representation or a concealment of material facts. 2. These facts must be known to the party estopped at the time of his said conduct, or *at least the circumstances must be such that knowledge of them is necessarily imputed to him.* 3. The truth concerning these facts must be unknown to the other party claiming the benefit of the estoppel, at the time when such conduct was done, *and at the time when it was acted upon by him.* 4. The conduct must be done with the intention, or at least with the *expectation* that it will be acted upon by the other

party or under such circumstances that it is both natural and probable that it will be so acted upon. There are several familiar species in which it is simply *impossible* to ascribe any *intention* or even *expectation* to the party estopped that his conduct will be acted upon by the one who afterwards claims the benefit of the estoppel. 5. The conduct must be relied upon by the other party, and, thus relying, he must be led to act upon it. 6. He must in fact act upon it in such a manner as to change his position for the worse; in other words, he must so act that he would suffer a loss if he were compelled to surrender or forego or alter what he has done by reason of the first party being permitted to repudiate his conduct and to assert rights inconsistent with it. It will be seen that *fraud* is not given as an essential requisite in the foregoing statement. It is not absolutely necessary that the conduct mentioned in the first subdivision should be done with a fraudulent purpose or intent, or with an actual and fraudulent intention of deceiving the other party; nor is this meaning implied by any of the language which I have used. The adoption of such an element as always essential would at once strike out some of the most familiar and best established instances of equitable estoppel. Undoubtedly, a fraudulent design to mislead is often present as an ingredient of the conduct working an estoppel, but this only renders the result more clearly just, and, if I may use the expression, more conclusive."

Again (*Ibid.*, p. 1445):

"With respect to the persons who are bound by or who may claim the benefit of the estoppel, it operates between the immediate parties and their privies whether by blood, by estate, or by contract."

Herman on Estoppel, Vol. I, p. 5, says:

"Sec. 7. The following are recognized propositions with respect to an estoppel *in pais:*

1. If a man, by his words or conduct, willfully endeavors to cause another to believe in a certain state of things which the first knows to be false and if the second believes in such a state of things and acts upon his belief, he who knowingly made the false statement is estopped from averring afterwards that such a state of things did not in fact exist.

2. If a man either in express terms or by conduct, makes a representation to another of the existence of a certain state of facts which he intends to be acted upon in a certain way and it is acted upon in that way, in the belief of the existence of such a state of facts, to the damage of him who so believes and acts, the first is estopped from denying the existence of such state of facts.

3. If a man, whatever his real meaning may be, so conducts himself that a reasonable man would take his conduct to mean a certain representation of facts and that it was a true representation and that the latter was intended to act upon it in a particular way, and he with such belief does act that way to his damage, the first is estopped from denying that the facts were as represented.

4. If, in the transaction itself which is in dispute one has led another into the belief of a certain state of facts, by conduct of culpable negligence calculated to have that result, and such culpable negligence has been the proximate cause of leading, and has led, the other to act by mistake upon such belief to his prejudice, the second cannot be heard afterwards as against the first, to show that the state of facts referred to did not exist.

5. Nobody ought to be estopped from averring the truth or asserting a just demand, unless by his acts or words, or neglect, his now averring the truth or asserting the demand would work some

wrong to some other person who has been induced to do something, or to abstain from doing something by reason of what he has said or done, or omitted to say or do."

Everest & Strode on Estoppel, 2nd Edition, pp. 14, 15, furnishes another contribution to the subject, as follows:

"Estoppels *in pais*, or equitable estoppels, as they have sometimes been called, are also of an importance which is growing daily, and far from being odious, are certainly equitable in their nature, and ought to be regarded with favor in courts of equity. Thus, in the case of The Citizens Bank of Louisiana vs. First National Bank of Orleans, L. R. 6 H. L., 352, Lord Selborne says:

'I apprehend that nothing can be more certain than this, that the doctrine of equitable estoppel by representation is a wholly different thing from contract, or promise, or equitable assignment, or anything of that sort. The foundation of that doctrine, which is a very important one, and certainly not one likely to be departed from, is this: That if a man dealing with another for value makes statements to him as to existing facts, which being stated would affect the contract, and without reliance upon which or without the statement of which, the party would not enter into the contract, and which, being otherwise than as they were stated, would leave the situation after the contract different from what it would have been if the representations had not been made, then the person making those representations shall, so far as the powers of a court of equity extend, be treated as if the representations were true, and shall be compelled to make them good.'

To the same effect are the remarks of Lord Blackburn in his judgment in the case of Burkenshaw vs. Nicolls, L. R., 3 App. Cir., 1004, where the learned judge says:

'Now sometimes there is a degree of odium thrown upon the doctrine of estoppel, because the same word is used occasionally in a very technical sense, and the doctrine of estoppel *in pais* has been thought to deserve the odium of the more technical class of homologation. But the moment the doctrine is looked at in its true light, it will be found to be a most equitable one, and one without which, in fact, the law of the country could not be satisfactorily administered. When a person makes to another the representation, "I take upon myself to say such and such things do exist, and you may act upon the basis that they do exist," and the other man does really act upon that basis, it seems to me it is of the very essence of justice that, between those two parties, their rights should be regulated, not by the real state of the facts, but by that conventional state of facts which the two parties agree to make the basis of their action; and that is what I apprehend is meant by estoppel *in pais* or homologation. But whether the term be used in its more or less technical sense, I take it that one common idea runs through the whole, namely, that your rights as between yourselves, must be regulated upon the basis, that that is accurate which you induced the other side to take as the basis upon which he was to act."

The above rather full quotations from the text writers are given because they represent the impartial conclusions reached by learned authors after careful and disinterested examination of the subject.

The text, in each instance, is supported by many cases o which we deem it unnecessary to here particularly refer.

The Commissioner of Patents is Regarded in the Patent Office and By the Courts as the Representative of the Public.

In the administration of the patent law it has always been held that the public, against whom the monopoly is effective, are represented, in the contract between the inventor and the Patent Office, by the Commissioner, whose duty it is to determine the right to the grant. For instance, in *Ex parte* Kephart (C. D., 1903, p. 137), it was held in regard to a public-use proceeding, that:

> "The protestant in public use proceedings has no authority to make a binding agreement as to what shall be considered evidence in the case. Such proceedings are not to be regarded as a contest between the protestant and the applicant, but as an investigation on *behalf of the public* by the Patent Office. U. S. *ex rel* National Phonograph Co. vs. Allen, C. D. 1902, p. 571. The parties in interest are *the applicant* on the one hand and *the public* on the other.
>
> The protestant does not represent the public and cannot make agreements for it. This office alone represents the public and its approval is necessary to make any agreement affecting the merits of the case binding."

Judge Baker, in Railroad Supply Co. vs. Hart Steel Co., 222 Fed., 274, defined a patent in the following language:

> "A patent is a contract between the Government *on behalf of the people* and the patentee. The grant of a patent might have been made conclusive evidence of its validity, except against suits by the Government for fraud or mutual mistake in the issuance.

> But the fact that certain defenses are left open to the individual should not make us lose sight of the nature of the presumption that attaches to the grant. Not merely has the application been examined *on behalf of all the people* by experts who have access to all the prior patents and publications of the world," etc., etc.

See also Fried. Krupp Aktien-Gesellschaft v. Midvale Steel Co., 191 Fed., 588-594, Buffington, J., and Grant v. Raymond, 6 Peters, 217-241, Marshall Ch. J.

That the Commissioner constantly acts for and on behalf of "all the people" in his dealings with applicants, and that the estoppel upon an applicant arising from the disclaimers, qualifications and limitations that he imposes upon himself when he accepts a patent may be availed of by any member of the general public who is attacked under the patent, is well established.

In New York Belting & Packing Co. vs. Sibley, 15 Fed., p. 386, the patentee was confronted in the Patent Office with an English patent as a reference and, in order to overcome its disclosure, he amended his claim by adding certain limitations. Later, when his patent was put in suit, he was held by the Court to a construction of it that accorded with his statements and conduct when prosecuting his application, the Court saying:

> "It has several times been decided by the Supreme Court that disclaimers, qualifications, and limitations imposed upon a patentee by the Patent Office, are forever binding upon him, if he chooses to accept a patent containing them. Not only are third persons likely to be misled to their injury by any subsequent enlargement by reissue or by a

broad construction of the claims thus intended to be limited, but these qualifications are conditions precedent, without which there would have been no grant at all, and, of course, the grant must be taken as it is given. * * * Construing the patent as we must according to the requirements of the Office acquiesced in by the patentee, the defendant does not infringe it, because his frame has not the peculiar construction which the Examiner declared was the only ground for issuing the patent."

The binding character of representations made by a patentee to the patent-granting authority acting for and in behalf of the public, and the availability of the estoppel created by such representations to any member of the public who is afterward pursued by the owner of the patent, is strikingly illustrated by the case of Union Manufacturing Co. vs. Lounsbury, *et al.*, 2 Fish. Pat. Cas., 389; 24 Fed. Cas., 587, decided by Judge Nathaniel Shipman, a great patent judge, in September, 1862.

The material facts of that case were as follows:

On July 15, 1829, a patent was granted to one John Arnold for an "Improvement in the Machines for Forming the Web of Cloth of Wool, Hair, or Other Suitable Substance, Without Spinning or Weaving." This patent expired by limitation (patents then running for only fourteen years) on July 15, 1843.

On October 20, 1836, another patent was granted to the same John Arnold and one George G. Bishop, for a joint invention of the two last named, relating to improvements in the same class of invention. This patent also expired by limitation on October 20, 1850.

In January, 1849, after the original Arnold patent had expired but just before the expiration of the Arnold and Bishop patent, Congress was petitioned by

the owners of both patents for the extension of both patents, as one. This petition was supported, from time to time, before a Committee of Congress, with perseverance, and finally, on March 29, 1856, an act was passed extending both patents, as one, for the further term of fourteen years from that date.

On March 18, 1856, the extended patent was reissued and suit was then brought upon it against the defendants, Lounsbury, *et al.* After a recital of the above facts the learned judge, in his opinion, said (p. 389):

> "The bill is founded upon the reissued patent and it becomes a vital inquiry whether or not this patent is valid. If it is not a valid patent, then the suit fails. If it is valid, and the respondents infringe, then they are liable to be enjoined. I have no doubt on this question. The patent of 1839, both in its original form and in that of the reissue, is invalid, because it did not and does not describe a practical invention. The conception of the inventor, in all the forms in which he attempted to reduce them to practice, proved useless and abortive, until 1836, when the joint invention of Arnold and Bishop was made. The proof of the utter worthlessness of the invention originally made by Arnold, is to be found in the evidence produced before the Court from the files of Congress, and upon which that body acted in granting the renewal. This evidence was presented and presented to that body by these complainants, and it presents conclusive proof, to my mind, that the original "invention was incomplete." And, after having obtained an act of Congress extending the two patents as "one invention," on the express grounds that the first one was no complete invention, within the meaning of the patent act, it is too late for these complainants to set up the contrary fact, and seek by injunction, to protect that which they have solemnly declared

to be worthless. The report of the committee, recommending the passage of the act says: 'No inconvenience can result to the public or injury to any individual, by the renewal and extension of the first patent, because the invention was imperfect, and a working machine could not be constructed except in connection with what is covered by the second patent.' This conclusion of the committee is supported by evidence presented to them and which has been adduced on this trial. After the legislature has acted upon this conclusion and passed the statute in question for the benefit of these complainants by granting them rights adverse to the public and to individuals, it would ill comport with the duty of a court of equity to aid them in reversing the facts, and thus working the very hardship which they had satisfied Congress could never exist.

Should it be said that this conclusion of the court only applies to the machine, and leaves the original process sheltered by the reissue, there are several answers. If this process is anything more than the function of the machine, it is a purely mechanical process wrought by the machine, and by the machine alone.

If no working machine could be made according to the invention of Arnold, then no process was ever successfully invented by him, for there is no evidence that he worked the process except by the machine. The intellectual conception of a possible process without a potential working of it out, is not patentable.

If an inventor merely conceives a mechanical process in his mind, and then sets to work to construct a machine to work that process and works it out in no other way, and the machine fails to work successfully, then his claim as the inventor of a process is as groundless as his claim as the inventor of a machine.

Arnold having failed to work this alleged process, except by his machine, both claims to 'inven-

tion,' in the sense of the patent act, fall to the ground.

But if it appeared that Arnold invented a mechanical process that could be distinguished from the function of his machine, and which could furnish a distinct ground of claim for an invention, still there is, in the judgment of the court, an insuperable difficulty in the way of these complainants availing themselves of it.

They represented to Congress, in the most solemn manner, that the invention of 1829 was incomplete and worthless of itself and of no value except in connection with the subsequent invention of 1836. They must, therefore, be deemed to have repudiated any claim to an invention by Arnold of a mechanical process, and to have abandoned it, if any such claim had ever existed in Arnold or themselves. Congress having passed the act for their relief, based upon the faith of these representations, equity and good conscience demand that they should be held to them."

This last mentioned case cannot be distinguished, in principle, from the one at bar.

There, the patent granting authority, acting for and on behalf of the public, was Congress itself; here, it was the Commissioner of Patents.

There, the representations to Congress of which the estoppel was predicated was the worthlessness and inoperativeness of the process of the patent of 1829; here, the representations to the Commissioner, were, first, the successful reduction to practice of the process by Rietzel establishing Rietzel's priority over the British and French Harmatta disclosures, by virtue of which the Rietzel patent was secured; and, secondly, the successful reduction to practice of the process by Rietzel, establishing Rietzel's priority over the disclosure of the U. S. Harmatta application by virtue of

which a judgment on the record against Rietzel and his assignee was averted; a standing on the question of priority was secured to Rietzel and his assignee; and the availability of the Rietzel patent against the public continued.

There, as here, the estoppel was urged by a member of the general public sued as an infringer, against one in privity with those who had made to the public agent the representations and declarations of which the estoppel was predicted.

The case constitutes an emphatic vindication of the principle now invoked by defendant in this Court of Equity, that a patentee or one in privity with him, will not be permitted to declare and represent one state of facts to the public or its representative, upon which the public or its representative acts to the detriment of the public, and to then subsequently repudiate these declarations and representations and assert a different and contradictory state of facts, as against a member of that same public.

No one can doubt that when the representations in question were made it was the intention and expectation that the Commissioner would gain the impression and form the judgment that Rietzel was the prior inventor over Harmatta, as well with respect to the process of welding plane-faced plates, face to face, as with respect to the process of welding plates provided with projections and that Rietzel's practice of the former process carried back to the year 1898. The estoppel cannot, therefore, be limited to the last named process. Had the representations been intended to extend only to such process there would have been no point in having mentioned the process of welding plane-faced plates by means of a pointed electrode

with such particularity and as the one first to be practiced by Rietzel.

That the Commissioner so understood the matter is clear from his grant of claims to Rietzel covering fully Harmatta's disclosure. The Trial Court sustained this defense and its treatment of the matter in its written opinion leaves nothing to be desired (pp. 42-50).

RIETZEL DID ACTUALLY ELECTRICALLY WELD PLANE-FACED PLATES IN SPOTS IN 1898.

Although the truth in regard to Mr. Rietzel's early work is immaterial to the defense of equitable estoppel just discussed, defendant, nevertheless, had the temerity to go into plaintiff's camp, summon Mr. Rietzel and put him on the stand in support of its other affirmative defense of prior invention by Rietzel (Rec., p 633).

Mr. Rietzel is still in the employ of the Thomson Company, as both he (Rec., p. 660; Rd-Q. 167) and the witness Clark (Rec., p. 262) had to admit. All that he had to say was evidently tinctured with the bias of interest. There were, however, some very material things he was obliged to admit, namely, that he was employed by the Thomson Electric Welding Company from August, 1888, to June 21, 1907 (Rec., p. 634, Q. 5) as foreman, superintendent, engineer and manager; that in July, 1898, he welded together plane-faced overlapped plates of metal, in spots, by the use of a flat electrode on one side of the plates and a pointed electrode on the other side (*Ibid.*, p. 635); that these electrodes were used in connection with a standard Thomson butt welding machine (*Ibid.*, p. 636);

that the welds made were subjected to various severe tests and found to be good welds (*Ibid.*, p. 638); that the meeting faces of the overlapped portions of the metal were plane, smooth faces; that his work involved a method of welding two plates or sheets of metal together, face to face, between electrodes, consisting in restricting the area of contact of an electrode with said plates to a spot, passing a heating electric current from said electrode to the co-operating electrode through said spot to heat the work to the welding temperature and applying pressure to the work in line with said spot to effect the welding of one plate to another; that the product or article produced by him consisted of metal plates fastened together by a number of distinct and isolated welds on their meeting surfaces and in spots comprising meeting portions of the metal plates, the backs of said plates being practically unaltered in their metallic condition and spots on the meeting surfaces being separated from one another by distinct unwelded areas (*Ibid.*, p. 635); that his contacts or electrodes were of copper (*Ibid.*, p. 637).

Under the questioning of counsel for plaintiff, Rietzel, of course, attempted to give the impression that his work in 1898 was fugitive, experimental and amounted to nothing. Having several times referred to his work as experimental, he was asked the following question on redirect examination (*Ibid.*, p. 659):

> "Rd-Q. 164. How do you reconcile your answers to X-Qs. 160 and 161 with the statements in your affidavit filed in your application for patent and executed on the 15th day of February, 1909, in which you say, 'That prior to the 18th day of February, 1904, he repeatedly, successfully practiced the methods of fastening two sheets of metal together face to face by welding them at spots

in their meeting surfaces by confining the heating electric current passed from one plate to the other in such spots and localizing the welding pressure at such spots * * * that work was repeatedly and successfully done in this manner upon various sizes and pieces of metal plates * * *.

That the work done by him as aforesaid, demonstrated the complete success of the operation and that metal plates could be successfully and firmly united together by distinct or isolated electric welds forming welded spots of union in their meeting faces and constituting in effect a successful substitute for a union of the same by a number of rivets.'

A. I can answer that by saying that I did weld various pieces of sheet metal together by using the pointed electrode as one and a flat electrode as the other, but only so far as I can remember now at the times mentioned, that is in July, 1898, and again in September or October, 1898, I considered some of the welds that I made satisfactory and successful, but did not consider it a commercial or practical experiment at that time."

The Court will, of course, have to decide which piece of evidence has the greater probative force, the testimony of Mr. Rietzel given, as a hostile witness, in a strenuous litigation, in 1919, or the affidavit of Mr. Rietzel given *ante litem motam*, in February, 1909, ten years earlier.

Of the two persons to whom Mr. Rietzel admits having explained his invention, one, Mr. Charles Osgood, is dead (Rec., p. 254, Q. 26) and the other, Mr. Clark, is still an employee of the Thomson Company and remembers nothing!

Mr. Rietzel, when on the stand, made a sketch illustrative of the work done by him in 1898 (Rec., p. 640). It is identified as "Defendant's Exhibit Rietzel

Sketch" and is reproduced in the record, p. 2041. Counsel for plaintiff endeavored to establish by the witness that welds applied in accordance with the showing of this sketch would, because the pointed electrode was placed initially close to the edge of the work, "squash out" the metal at the edge. Here, again, the evidence of the affidavit of 1909, drawn by counsel for the Thomson Company ten years earlier, must be considered. It says (Rec., p. 646):

> "That the work done by him, as aforesaid, demonstrated the complete success of the operation and that metal plates could be successfully and firmly united together by distinct or isolated electric welds forming welded spots of union in their meeting faces and constituting in effect a successful substitute for a union of the same by a number of rivets."

This affidavit was filed to support such claims of Rietzel as the following, for instance (Rec., p. 1770):

> "6. The method of uniting sheets of metal by pressing them together and at the same time passing a heating and welding current from one to the other at a spot on their meeting surfaces, which is restricted in area throughout the operation so as to leave on the meeting surfaces a well defined and comparatively extensive area of no union completely surrounding said spot."

And this (Rec., p. 1799):

> "24. Sheet metal plates electrically welded together by heating current and pressure at a spot or spots definitely located in and involving the heated material of the opposed or meeting portions of the plates entirely surrounded by distinct areas unwelded, as and for the purpose described."

Furthermore, Mr. McBerty, while on the stand, before his Honor Judge Killits, produced samples of welding showing that welding may be done with the pointed electrode close to the edge of the work, without producing any "squashing out" of the metal (Rec., p. 764, Q. 296). (Defendant's Exhibit Y.)

Mr. Rietzel gave a reason why the spot welding of plane-faced plates was not mentioned in his application filed in February, 1905, as follows (Rec., p. 641):

> "Q. 57. I notice that this application was filed in February, 1905, and illustrates in its drawings more particularly the formation of spot welds by the use of projections between the proximate faces of the sheets. Do you know of any reason why you did not mention in the application for this patent the spot welding of sheets without projections between the proximate faces?
>
> A. Well, I might explain that by saying that at that time, that is, the period between 1896 and 1904 it was not the policy of the Thomson Electric Welding Company to apply for patents of any kind until such time as they had, or would expect in the immediate future, to receive an order for an electric welding plant for any particular or special purpose before applying for patents and as during the period between the fall of 1897 and the year 1904 we did not receive or have any problems put up to us by which use might be put to some of those experiments which I did in 1898 as regards the welding in spots, but in 1904 we had occasion to apply on a particular class of work the method of raising projections on the work to be operated on. As this proved highly successful at the very start it was decided to make application for patents on this subject-matter."

If the whole truth were told about this matter it would doubtless appear that the reason that the weld-

ing of plates having projections was disclosed and the welding of plane-faced plates was not disclosed was the belief, at that time, that there was no patentable invention in the welding together of plane-faced plates and, therefore, no point in mentioning that such a thing had been or could be done.

Not only did the Rietzel application, as originally filed, make no disclosure of the welding together of such plane-faced plates, face to face, but it contained no claim broad enough to include and cover such a process (Rec., p. 1727).

Examination will show that original claims 1, 2 and 3 were each limited to a process that involved the *simultaneous* making of a *multiplicity* of distinct welds at a *multiplicity* of contact points, and that claims 4, 5, 6, 7 and 8, constituting the remainder of the original claims, were each limited to a method of welding involving the formation of distinct projections on the plates, by indenting, or otherwise.

It was not till the citation by the Patent Office of the British patent of Harmatta, on the 8th day of June, 1908, *nearly three years after the application of Rietzel was filed,* that Rietzel began to file claims that were inclusive of Harmatta's disclosure of the welding of plane-faced plates, face to face, and that covered Rietzel's similar early work. The following is typical of the first effort to put forward such an inclusive claim, to-wit, on Nov. 30, 1908 (Rec., p. 1770):

> "6. The method of uniting sheets of metal by pressing them together and at the same time passing a heating and welding current from one to the other at a spot on their meeting surfaces which is restricted in area throughout the operation so as to leave on the meeting surfaces a well defined and comparatively extensive area of no union completely surrounding said spot."

It was to support these broad inclusive claims that Rietzel's early work of 1898 in the spot welding of plane-faced plates, face to face, was harked back to to accomplish the "short circuiting" of Harmatta, whose date of invention was known then, to be at least as early as 1904, the effective date of his British patent, and was presumed to be earlier still, if by any chance, he had pending a United States application—which, it subsequently turned out, he had!

Before leaving this affirmative defense of prior invention by Rietzel, we would remark, that if the affidavits of Rietzel put forward by the Thomson Company did not really tell the truth, but were false and misleading, and intended so to be, then there is, indeed, greater reason for sustaining the defense of equitable estoppel. If a statement of facts believed and offered *in good faith*, may, nevertheless, operate as an estoppel, by how much greater reason should a statement of facts *known to be false*, have that effect.

WHAT HARMATTA THOUGHT HE HAD INVENTED AND WHAT HE SOUGHT TO PATENT

No doubt Mr. Harmatta would be very much surprised to learn what plaintiff now contends was the invention for which he originally solicited a patent.

By a process of elimination and suppression, on the one hand, and of expansion, on the other, the things claimed by him as of his invention in his original application have been entirely displaced by claims for processes and products which he not only never claimed to have invented, and never swore to, but never claimed nor suggested as inventions at all!

In the record will be found a certified copy of the application as originally filed by him and of all amend-

ments made to it (Rec., p. 1354), and also a detached, line for line, copy of the original application (Rec., p. 1156) and a copy of the original drawing (*Ibid.*, p. 1166) printed separately.

Apparently, the only prior electric welding art known to Harmatta at the date of his original specification was (1) the process of electric arc-welding exhibited, for instance, in the United States Benardos and Olzewski patent No. 363,320 (Rec., p. 1030) of 1887, wherein no pressure at all was exerted on the work by the current-carrying electrodes, and (2) the process of electric resistance-welding disclosed in the original Thomson "Art" patent No. 347,140 of 1886 (Rec., p. 1021), wherein pressure was applied directly to the whole surface of the pieces or parts to be united through the medium of electrode clamping jaws, for the original Harmatta specification states (p. 2, Rec., p. 1357):

> "According to none of the present known electric welding processes are the articles to be welded firmly pressed together during the welding operation by one or both electrodes, for the purpose of favoring welding. Hitherto either no pressure has been exerted at all, or it has been exercised at a certain distance from the place of welding, or at all events not centrally direct upon the electrodes pressing on the place to be heated. In short, hitherto direct electric welding pressure has never been exercised by means of the electrodes located in the direction of the current directly above the surface or point being welded."

The specification then goes on to point out that various means may be employed for exerting the necessary pressure required by the alleged new process (p. 2):

> "For carrying out the new process various apparatus may be employed, as the necessary pressure may be exerted at the place of welding by the aid of any of those technical means which are suitable for producing or transmitting pressure; *e. g.*, with a press either direct or by means of indirect transmission by levers. Or it may be by means of simple hand levers, that is to say, by means of direct or indirect manual power."

And then comes a description of the various forms of electrodes that may be employed for applying the pressure. Figs. 1 and 5 are referred to as illustrating the use of one form of electrode that will serve; and Figs. 2 and 3 another form of electrode; Fig. 4, another form; and Fig. 6, still other forms.

Referring to the forms of electrodes shown in Figs. 1 and 5, the specification states (p. 2):

> "Fig. 1 is a view illustrating the welding of two metal sheets of equal thickness, intermittently or at certain spots only.
>
> * * * * *
>
> Fig. 5 is a side elevation of a welding device (also illustrated in part in Fig. 1) according to which the pressure is exercised by pin-shaped electrodes, the form of which may be suited to the particular purpose in view, and which may be adapted to work on the smallest possible surface of contact."

And referring to the form of electrode shown in Figs. 2 and 3, the specification says:

> "Fig. 2 is a front elevation and
> Fig. 3 a side elevation of a device which may be employed for continuous welding, the pressure being exerted by roller electrodes, whereby the advancing series of single points of the seam to

be welded is united to a whole with a minimum consumption of current."

It is perfectly apparent that Blumuttz regarded both these forms of electrodes as operating upon precisely the same principle, as indeed they do. The pin form of Figs. 1 and 5, of course, applied pressure to the work at but a single point at a time with a minimum consumption of current, and to make plain that the roller electrodes operated similarly, the specification industriously stated, as we have already seen, that where the pressure is applied through such roller electrodes,

"the *advancing series of single points* of the seam to be welded is united to a whole with a minimum consumption of current."

There was, apparently, a studied attempt on Blumuttz's part to show, as closely as possible, that the welding of the plates at a series of points so close together as to cause a merging of the welding was not essentially different from the welding of the plates at separated, isolated points.

In either case, there was, as expressed in the quoted part of the specification, "a minimum consumption of current."

To have welded the whole length of the seam at once, by flat electrodes that extended from end to end, would have obviously required a very larger amount of current, but by using rollers that operated upon the plates at one point only at a time, practically the same economy of current was effected as when pointed electrodes applying current at but one point at a time, were employed.

Nor was any distinction, in principle, in the construction of the different forms of electrodes, made in the original claims.

The first two claims were relatively broad and inclusive. They read as follows (Rec., p. 130):

> "1. The process of electric welding, consisting in employing the electrodes not only to conduct the current to the objects being welded, but also to exert a repulsive pressure on the same, substantially as described.
>
> 2. An electrode apparatus for electric welding, comprising two electrodes between which the objects to be welded are introduced, and means whereby one of the electrodes can be approached to and receded from the other, substantially as described."

Both of these claims apply equally to the gun electrodes of Figs. 1 and 3 and to the roller electrodes of Figs. 2 and 4, and were evidently intended to do so.

The two remaining claims were specific to the roller electrode apparatus *per se*, and read as follows:

> "3. An electrode apparatus for electric welding, comprising two roller electrodes between which the objects to be welded are introduced, and means for pressing the electrodes to the work, substantially as described.
>
> "4. An electrode apparatus for electric welding, comprising two roller electrodes between which the objects to be welded are introduced, means for pressing the electrodes to the work, and means for rotating one or both of the rollers for the purpose of advancing the work in its path between the electrodes, substantially as described."

On January 5, 1903, all these claims were rejected. On May 18, 1903, attorneys for Hornaday replied

to this rejection by striking out the original specification and claims and filing a new amended specification and a single claim (*Ibid.*, p. 1367) and by striking out the original drawing and substituting a new drawing (*Ibid.*, p. 1373).

This amendment eliminated all showing of the roller electrode apparatus from the application and it was never thereafter reintroduced, which accounts for its absence in the Harmatta patent, as finally issued.

The new claim introduced in connection with the substitute specification last referred to read as follows (*Ibid.*, p. 1373):

> "The process of electrically welding thin sheets and the like, consisting in applying pressure at the place of welding of the two superposed metallic objects to be united, for the purpose of effecting thorough superficial contact between them, and then, whilst maintaining the said pressure, heating the objects by passing an electric current through them, substantially as described.'

On August 10, 1904, this claim was rejected on patent to Blevins, No. 758,503, of April, 1904. (*Ibid.*, p. 1374.)

On Nov. 26, 1904, the former claim proposed was stricken out and the following new claim filed, limiting the invention to the welding of sheets of two millimeters (about 2-25ths of an inch) or less in thickness (*Ibid.*, p. 1375.)

> "The process of electrically welding thin metallic sheets and the like, from about two millimeters in thickness downward, consisting in first pressing intimately together the two superposed metallic objects at the very point in which the

welding joint is to be formed, and then, whilst maintaining the intimate pressure, heating the objects by passing an electric current through them exactly at said point, in which the welding is to be effected, substantially as set forth."

This claim was, on March 30, 1905 (Rec., p. 1380) rejected on the so-called roller welding patent to Thomson, No. 444,928, of 1891 (*Ibid.*, p. 1047) and the so-called soldering patent to Thomson, 496,016 (*Ibid.*, p. 1053.)

On Nov. 17, 1905, another amendment was filed canceling the last quoted claim and substituting two new ones therefor, each also limited to the welding of plates of two millimeters or less in thickness (*Ibid.*, p. 1384).

These claims were, on Dec. 1, 1905, also rejected on the aforesaid Thomson patents, the Examiner stating (*Ibid.*, p. 1388):

"As described in patent 444,928, the plates to be welded are pressed together by means of the screw S, thus forming an electrical contact between them, the electric current is then turned on for the purpose of heating the plates and forming a weld between them—see the description in lines 84 to 94, page 1 of said patent."

On May 18, 1906, the claim last before presented was canceled and another substituted (by newly appointed attorneys, Messrs. O. E. Duffy & Son), reading as follows (*Ibid.*, p. 1395):

"1. The process of electrically welding thin metallic sheets and the like consisting in applying suitable electrodes on the metallic objects at the very point at which the welding joint is to be

formed, then causing said electrodes to exert a pressure on the metallic objects sufficiently to press the metallic objects intimately together at the point at which the welding joint is to be formed, then heating the metallic objects by passing an electric current through said electrodes and through the metallic objects, maintaining the pressure of said electrodes on the metallic objects during the passage of the electric current through the electrodes and metallic objects."

This claim also was, on June 7, 1906, rejected on the Thomson patents Nos. 496,019 and 444,928 of record (*Ibid.*, p. 1396).

On Dec. 3, 1906, the specification and claim were canceled and a new specification and claim filed (*Ibid.*, p. 1399).

The new claim read as follows (*Ibid.*, p. 1403):

"The process of electrically welding thin metallic sheets, consisting in applying suitable electrodes on the metallic sheets at the very point at which the welding joint is to be formed, then causing said electrodes to exert a pressure on the metallic sheets sufficiently to press the metallic sheets intimately together at the point at which the welding joint is to be formed, then heating the metallic sheets by passing an electric current through said electrodes and through the metallic sheets, and maintaining the pressure of said electrodes on the metallic sheets during the passage of the electric current through the electrodes and metallic sheets."

This claim was also rejected on the Thomson patents 496,019 and 444,928, of record, and also on the Blevins patent No. 758,503 (*Ibid.*, p. 1404).

On Dec. 4, 1907, or nearly a year after the last rejection, another amendment was filed striking out the

former claim and presenting two new ones, reading as follows (*Ibid.*, p. 1405):

> "1. The process of electrically welding a plurality of metal sheets, consisting in exerting a heavy mechanical pressure by means of electrodes on said sheets, thereby flattening, smoothing out and eliminating all irregularities and intimately pressing said sheets together, whereby air space and interstices between said sheets are eliminated subsequently passing an electric current through the sheets thus softening and welding same while maintaining the heavy pressure of the electrodes on the sheets.
>
> 2. The process of electrically welding thin metallic sheets, consisting in applying suitable electrodes on the metallic sheets at the very point at which the welding joint is to be formed, then causing said electrodes to exert a maximum pressure on the metallic sheets sufficiently to press the metallic sheets intimately together at the point at which the welding joint is to be formed, then heating the metallic sheets by passing an electric current through said electrodes and through the metallic sheets, and maintaining the maximum pressure of said electrodes on the metallic sheets during the passage of the electric current through the electrodes and metallic sheets."

These claims were, on January 6, 1908, also rejected on the Thomson patents of record (*Ibid.*, p. 1408).

On the 6th day of January, 1909, being the last day of the year allowed by statute within which to take action to avoid abandonment (4894 R. S., U. S.) a formal amendment to claim 1 last presented was made and a reconsideration of both claims requested (*Ibid.*, p. 1409). Both claims were, however, on February 9, 1909, rejected on the Thomson patents 444,928 and 496,016, and the Blevins patent 758,503 already cited in the case.

In his letter of February 9, 1909, last above referred to, the Examiner (who had already allowed the Rietzel application with claims covering Harmatta's disclosure apparently, began to think he was not giving Harmatta a square deal) stated (*Ibid.*, p. 1411):

> "It is thought that if there is any patentable matter in this case it resides in the securing of the sheet metal parts together by means of the small round, sharply-defined place of welding which answers the purpose of a rivet, as is set forth on page 6 of the original specification."

On January 28, 1910, nearly a year later, another substitute specification, claims and drawing were filed, the claims reading as follows (*Ibid.*, p. 1416):

> "1. The process of electrically welding thin metallic sheets, consisting in securing the sheet metal parts together by means of a small round, defined place of welding which answers the purpose of a rivet.
>
> "2. The process of electrically welding thin metallic sheets, which consists in introducing the sheet metal parts to be welded between electrodes having the form of pins, pressing said electrodes firmly together and closing the circuit, whereby the specified small round, very sharply defined place of welding which answers the purpose of a rivet is obtained, substantially as set forth."

Between the date of the Examiner's aforesaid suggestion of the possible existence of patentable subject-matter in Harmatta's case, to-wit, February 9, 1909, and the date of the response of Harmatta's attorney thereto, to wit, January 28, 1910, the application for the Rietzel patent was allowed, and the Rietzel patent, on the 20th day of July, 1909, actually issued, with its

broad claims covering the Harmatta disclosure, completely. Then, in acting upon the Harmatta amendment of January 28, 1910, the Examiner, rather naively stated, in a communication dated March 22, 1910 (*Ibid.*, p. 1418):

> "Claims 1, 5, 6, 16, 17, 18, 19 and 20 of the patent to Rietzel, 928,701, July 20, 1901 (219-10) are suggested to applicant in accordance with the provisions of Rule 96 for the purposes of interference. He is required to make these claims on or before May 3, 1910, otherwise he will be considered to have disclaimed the subject-matter thereof in accordance with Rule 96 and the claims now in the case will be rejected as covering nothing patentable over such disclaimer."

Patent Office Rule 96 referred to reads as follows:

> "96. Whenever the claims of two or more applications differ in phraseology, but cover substantially the same patentable subject-matter, the Examiner, when one of the applications is ready for allowance, will suggest to the parties such claims as are necessary to cover the common invention in substantially the same language. *The Examiner will send copies of the letter suggesting claims to the applicant and to the assignees, as well as to the attorney of record in each case.* The parties to whom the claims are suggested will be required to make such claims and put the applications in condition for allowance within a specified time in order that an interference may be declared. Upon the failure of any applicant to make the claim suggested within the time specified, such failure or refusal shall be taken without further action as a disclaimer of the invention covered by the claim, and the issue of the patent to the applicant whose application is in condition for allowance will not be delayed unless the time

> for making the claim and putting the application in condition for allowance be extended upon a proper showing. If a party make the claim without putting his application in condition for allowance, the declaration of the interference will not be delayed, but after judgment of priority the application of such party will be held for revision and restriction, subject to interference with other applications."

It would seem to have been fairer for the Examiner to have suggested these Rietzel claims to Harmatta before the Rietzel patent had been permitted to go to issue. It certainly was within his power to have done so under the provisions of this Rule 96. But, for reasons that will probably never be known, he did not do it; and when, on March 31, 1910, Harmatta's attorney presented an amendment incorporating, not only the suggested claims 1, 5, 6, 16, 17, 18, and 19, but five additional claims, as well, of the Rietzel patent (which number was ultimately increased by the addition of three claims more) (*Ibid.*, p. 1427), the Examiner did finally declare the interference it carried eight (8) counts (*Ibid.*, p. 1425), to which, by a second declaration, made later, were added three (3) counts more (*Ibid.*, p. 1430).*

The thing, however, that stands out prominently in the whole transaction is the fact that nothing patent-

*These claims were put in without a supplemental oath and have consequently never been sworn to by Harmatta. They were introduced more than five years after the imported foreign machines had been put into public use by The National Enamelling & Stamping Company and over two years after spot welding machines made by the Winfield Company and others had been put upon the market.

In the case of *ex parte* Lillie, 53 O. G., 2041, Commissioner of Patents Mitchell (than whom a sounder patent lawyer never lived) in criticising an attempt to enlarge a case by amendment after a long lapse of time, without the support of a supplemental oath, said:

ably new was discovered in Harmatta's case until it had been unsuccessfully prosecuted for between six and seven years and until after the Thomson Company's lawyers had, in the Rietzel case, convinced the Patent Office officials of the patentability of the disclosure of Rietzel and that Rietzel's invention antedated the effective dates of the Harmatta foreign patents.

After the decision of priority in favor of Harmatta, in the interference between the Rietzel patent and the Harmatta application—brought about, as we have seen, by the default of the Thomson Company and its failure to take testimony in behalf of Rietzel—the Harmatta application was again revised—not by O. E. Duffy & Sons, as would appear on the face of the record, but by H. C. Townsend, Esquire, the lawyer who wrote the original Thomson "Art" patent of 1886, and also the Rietzel patent, and who, notwithstanding, is afraid to state what "spot welding" is (Rec., p. 628)—and in it were incorporated many of the method or process claims and all of the article or product claims of the Rietzel patent; with the net result that when the Harmatta patent issued to the Thomson Co. on December 3, 1912, as a patent for seventeen years from that date, the Thomson Company had already, through its possession of the Rietzel patent (obtained by its representations of Rietzel's

"Another reason for the requirement of seasonable amendment is that courts look with disfavor upon attempts to enlarge the scope of an application once filed (Railway Co. vs. Sayles, 97 U. S., 554); and delay in filing amendments which enlarge the scope of the application as first filed, especially if they would operate to the prejudice of intermediate inventors, raises a presumption that the original application correctly set forth the scope of the invention then made, and that the additions or variations disclosed by the amendments are of late discovery. (Robinson on Patents, Sec. 561; see also Consolidated Electric Light Co. vs. McKeesport Light Co., 49 O. G. 1536 40 Fed., 21)."

priority over Harmatta) enjoyed the monopoly of the same subject-matter for over three years and a half, giving that Company an aggregate monopoly of twenty and one-half years, which, we respectfully submit, hardly squares with a Court of Equity's notion of fair play to the public.

THE HARMATTA PATENT

We have hereinbefore undertaken to analyze and discuss the disclosure of the Harmatta application as originally filed, drawing specific attention to the fact that all that Harmatta *therein* claimed and swore to as his invention, and, we may now add, all that he ever claimed and swore to *anywhere* as his invention, was, broadly (1) the process consisting in employing electrodes not only to conduct the current to the objects being welded, but also to exert a regulable pressure on the same, as carried out either by pointed electrodes, or roller electrodes, and (2) an apparatus for electric welding involving, specifically, the use of roller electrodes, both of which subjects-matter were clearly and indubitably anticipated, for instance, by the Thomson roller electrode patent No. 444,928, of January 20, 1891, upon which the application was repeatedly rejected.

We come now, to consider the patent itself, granted after the application had been kept pending for ten years, after the practical art had been fully developed by others, after the Rietzel patent had been granted, and after judgment against Rietzel, by default, had been secured by the deft manipulations of the Thomson Company.

Bearing in mind what the original application as filed showed and described, the first thing that strikes

us in examining the patent is the entire absence of any allusion to the use of roller electrodes. From both description and drawings the roller electrode apparatus, which figured so conspicuously in the original, has been entirely eliminated.

This was really done, of course, most foxily, for the purpose of avoiding comparison with the Thomson roller welding process; but is now attempted to be explained on the theory that while resistance-welding with one or more pointed electrodes is practicable, resistance-welding by means of one or more roller electrodes is entirely impracticable, thereby rendering the former patentable and the latter unpatentable!

The difficulty about this explanation is, however, that it is at war with the facts of record, that is to say:

(1) The Thomson patent No. 444,928 of January 20, 1891, taken and owned by the Thomson Electric Welding Co., shows and describes the use of such roller electrodes as practicable.

(2) The Lemp patent, No. 553,923, of February 4, 1896, also taken by the Thomson Electric Welding Company, shows and describes the use of such roller electrodes as practicable.

(3) The Harmatta British patent (Rec., p. 1124), the Harmatta (Egel) French patent (*Ibid.*, p. 1140), and the Harmatta Canadian application (Rec., p. 2043), all set forth the use of roller electrodes as practicable.

(4) Mr. Gravell, plaintiff's expert, admits that roller electrodes are practicable (Rec., p. 103, X-Q. 191, p. 104; X-Q. 199, *et seq.*).

(5) Mr. Geo. W. Knapp, plaintiff's witness, testifies that he successfully used roller electrodes (Rec. p. 221, X-Q. 27, *et seq.*).

(6) Mr. Geo. W. Knapp, Jr., plaintiff's witness, testifies to the same effect (Rec., p. 233, X-Q. 20, *et seq.*).

(7) Mr. Robert W. Clark, another of plaintiff's witnesses, testifies to the same effect (Rec., p. 263, X-Q. 114, *et seq.*).

(8) Prof. Thomson himself testifies to the practicability of welding by roller electrodes as carried out by his patent, 444,928, and states the same to be in extensive use (Rec., p. 533, Q. 28).

(9) And Mr. Dyer, defendant's expert, testifies to the entire practicability of roller electrodes and to the repeated successful use of the same by him (Rec., p. 583, p. 597, *et seq.*).

The next thing that attracts our attention is the new matter which the specification of the patent discloses.

On page 1, line 12 of the specification, we find a statement to the effect that the invention consists "also in the new article provided thereby." There is nothing in the original indicating that Harmatta ever supposed he had invented a new article. He neither described nor claimed such.

The matter on page 1, lines 34 to 97, inclusive, is, in its entirety, new matter. It is what Mr. Townsend, the draftsman of the amended specification, put in in October, 1912, not what Harmatta approved of and swore to in 1903.

This is the new stuff (p. 1, lines 34 to 97, Rec., p. 388):

> "It has been before proposed to electrically weld two rods of metal together by a butt welding process, the area of union effected being substantially co-extensive with the cross section of the pieces at their meeting ends, that is to say, the weld has been made over substantially the whole area of the opposed portions of said pieces. It

has also been proposed to make a lap joint between the ends of two strips of metal by electrically uniting them together over substantially the whole area of the lapping surfaces.

A weld formed according to my invention is distinguished, however, from such prior welds, among other things, by the fact that the opposed surfaces available for uniting the pieces together and in which it might be possible to form a weld are welded in a small spot or spots only, the spot or spots being surrounded by comparatively large areas of opposed surfaces in which no weld is made.

By the term 'electric welding' as used herein I mean that well-known process in which the work is brought to the welding temperature by internal heat generated by the resistance of the work itself to the passage of an electric current at the place of contact between the parts to be joined by the welding pressure, and I disclaim those processes of fastening pieces of metal together in which the parts are heated and practically melted down by an electric arc generated on the back of the piece by 'drawing' an arc by means of the electrode, as well as other processes in which the welding heat is generated externally and electrically in a resistance material and is imparted to the work by heat conduction from said resistance material in contact with the work.

While it is possible, consistently with my invention, to localize the desired pressure and heating current at the desired distinct small spot or area in various ways, this may be accomplished conveniently by pressure applied over the spot and itself localized on the back of the plate or sheet immediately over the small spot in which the union is to be made by using a tool pressed against the work by its end and formed at such end so as to engage the work by a spot or area of small extent and serving, likewise, by preference, as the electrode which feeds the current into the work

> to heat the same. The member which feeds the electricity being thus at the same time the tool, in this manner the most favorable conditions of working possible are secured, since as is well known, in really effective welding processes the place of welding brought to the proper temperature must be at once well hammered or pressed in order that the welding may be thorough."

The reference to the prior art is, of course, here but partial. It attempts to put out of the running welding by roller electrodes, though that was the principal thing disclosed and claimed by Harmatta originally, and, before him, by Thomson.

The statement as to "the spot or spots being surrounded by comparatively large areas of opposed surfaces in which no weld is made" was borrowed bodily from the Rietzel patent and finds no counterpart in the original Harmatta description.

The definition of electric welding "as used herein" as consisting of the "process in which the work is brought to the welding temperature by internal heat generated by the resistance of the work itself to the passage of an electric current at the place of contact between the parts to be joined," as distinguished from "other processes in which the heat is generated externally and electrically in a resistance material and is imparted to the work by heat conduction from said resistance material in contact with the work"—is wholly unwarranted by the original.

The original does not tell us of what material the electrodes are to be composed—does not say whether they are to be of high resistance or low resistance; does not say that they are of less resistance than the work; does not say that the heat is generated by resistance of the work itself or by the passage of the

current at the place of contact; and does not say that the heat is not generated externally in the electrodes and carried by heat conduction to the work. The disclosure of the original is quite consistent with the use of electrodes of relatively high resistance as suggested by the Benardos German patent, the Thomson patent 496,019, and the Stanley patent.

What Mr. Townsend, the draftsman of the Harmatta patent, wished the patent to show was that Harmatta appreciated and disclosed all of the essential principles and requirements of the most up-to-date application of resistance welding to the union of plates, and he, therefore, proceeded to make a description that would fill the bill, utterly regardless of the fact that in so doing he was setting forth that which Harmatta himself had never been guilty of disclosing or fathering, much less of swearing to.

Other examples of the interpolation of new substantive matter are found on page 2 of the specification. For instance, on lines 49 to 54 occurs the following:

> "And the circuit is closed by any suitable means thus producing a flow of heating current through the work itself *substantially localized therein* so as to bring the same to the necessary welding temperature at the desired spot only,"

for which there is no predicate in the original.

Again, lines 69 to 82, is wholly new matter, viz.:

> "The time or duration of pressure and heating and the amount of pressure as well as the volume of current for effecting the weld can be readily determined by experiment for different sizes or thicknesses of metal and as well understood in the art of electric welding to which my invention relates.

> "The operation is completed with the cutting off of the flow of current in the usual manner practiced in the art of electric welding and the withdrawal of pressure when desired to permit the work to be withdrawn from position between the electrodes."

And the description of the article produced is also wholly new, viz. (p. 2, lines 83 to 91, inclusive):

> "Sheet metal work made by this process is readily distinguished from that made by prior processes by the comparative absence of burning, roughening or disintegration of the material on the back of the plate when the operation is carefully conducted. It further possesses the advantage that there are no rivet heads to mar the finish of the back or outer surfaces of the plate."

As we have already pointed out, there was neither a specific description of, nor a claim for, the work or article in the original.

The Product or Article Claims of the Harmatta Patent Are Invalid Because for New Matter Never Sworn to By Harmatta to Be of His Invention.

The last five claims of the Harmatta patent, viz., claims 17, 18, 19, 20 and 21, are, in form, for products or articles of manufacture. They read as follows (Rec., p. 391):

> "17. Metal plates fastened together by a number of distinct or isolated welds on their meeting surfaces and in spots comprising meeting portions of the metal plates, the backs of said plates being practically unaltered in their metallic condition and the spots on the meeting surfaces being

separated from one another by distinct unwelded areas.

18. Sheet metal work comprising pieces of sheet metal welded together in the material of their meeting surfaces and in spots only, each surrounded by distinct areas of unwelded union, the back surfaces of said pieces being substantially unaltered over the welded spots, substantially as and for the purpose described.

19. Composite metal work having its component pieces welded together in spots only involving the material of their opposed or meeting surfaces, said spots being each entirely surrounded by distinct areas of unwelded union and the portion of the pieces back of the welds being substantially unaltered as and for the purpose described.

20. Metal work comprising a metal plate fastened on its surface to the opposed surface of another piece of metal by a weld at a spot only in the material of the opposed surfaces, said spot being surrounded by a distinct area of unwelded union and the back surface of said plate being practically unaltered over said spots, as and for the purpose described.

21. A metal article comprising two bodies of metal having adjacent plane surfaces united at a plurality of spaced and isolated spots of integral and autogenous welded union, the metal at the spots of welded union having substantially the same qualities as at other points."

These claims first appeared in the application for the Rietzel patent. Claim 17 was claim 16 in the Rietzel application and was introduced there by amendment of March 13, 1909 (Rec., p. 1798); claims 18, 19 and 20 were claims 17, 18 and 19, respectively, of the Rietzel application and were introduced there by the amendment of May 7, 1909 (*Ibid.*, p. 1807); and claim 21 was claim 20 of the Rietzel application and intro-

duced there by amendment of June 23, 1909 (*Ibid.*, p. 1814).

When the Harmatta application was sworn to and filed in 1903, it contained no claims at all to a product or article. As we have seen, of the four claims originally presented one was for a method or process and three for machine or apparatus.

It was not till March, 1910, over six years later, and after the Rietzel patent had issued, that the claims, copied word for word from the Rietzel patent, were inserted by amendment in the Harmatta application and the interference between Harmatta and Rietzel declared.

Comparison of the Harmatta patent with the Rietzel patent will disclose that claims 17, 18, 19, 20 and 21 of Harmatta and claims 16, 17, 18, 19 and 20 of Rietzel are identical.

Under Section 4886 of the Revised Statutes of the United States, patentable subjects-matter are divided into "art (process), machine, manufacture or composition of matter." These subjects are regarded as so distinct that a patent for a machine may not be reissued to cover a process (Eachus vs. Broomall, 115 O. G., 429), and a patent for a process may not be reissued to cover a product (Powder Co. vs. Powder Works, 98 U. S., 126), since in neither case will the reissue be for "the same invention."

Now, Harmatta applied for and claimed (1) a certain process (and not that claimed in his patent), and (2) a machine. He never swore to have invented anything else.

The introduction of claims for a product or article by his solicitors was unwarranted, just as was the introduction of a process claim in an apparatus application in American Lava Co. vs. Steward, 155 Fed., 731-

736, 738 (C. C. A-6); Steward vs. American Lava Co., 215 U. S., 161. This point was sustained by the trial court (Rec., pp. 41-42).

The Product or Article Claimed By Harmatta is Indistinguishable From That Claimed By Rietzel and Plaintiff is Estopped to Contend to the Contrary.

As we have seen, the product or article claims of the Harmatta patent were first put into the *Rietzel* patent by the Thomson Company's lawyer, Mr. Townsend, after knowledge of Harmatta's foreign patents had been brought home to him, and after the art of electrically welding plane-faced metal plates had been fully developed commercially by others than Harmatta. They were put into the *Harmatta* patent by the same skillful practitioner, with a view to again covering such product or article in the most complete manner possible, whether resulting from the welding of plane-faced plates or plates one or both of which were formed with slight projections.

It is significant that with all his ingenuity, Mr. Townsend was then, unable to describe the product or article made by the use of the Harmatta apparatus so as to distinguish it from the product or article made by the Rietzel apparatus. In other words, he regarded the two products as practically indistinguishable, as indeed they are.

By adopting the claims from Rietzel, who only *illustrated* the welding of plates provided with projections, and provoking an interference with Rietzel with respect thereto, and obtaining a judgment on that basis, plaintiff's predecessor and those claiming under him, including the plaintiff, are now estopped to assert that the said claims cover only a product or article re-

sulting from the welding of plane-faced plates, and not a product or article resulting from the welding of plates, one or more of which are provided with projections.

Here, again, the plaintiff is not permitted to blow hot and then cold. The same interpretation that was given the claims when they were obtained must be now given them when they are sought to be enforced against this defendant.

Inasmuch, therefore, as the present claims of Harmatta cover a product formed from plates having (one or more of them) pre-formed projections through which the welds are formed—which plaintiff is estopped to deny—it follows that such claims are all invalidated by the prior Robinson and Kleinschmidt patents which show products of this character.

THE PRIOR INVENTION OF SEBASTIAN ZIANI DE FERRANTI

The prior invention of Sebastian Ziani de Ferranti, of London, England, as disclosed in the Provisional application forming part of his British Patent, No. 11,921, of 1903, filed May 25, 1903 (Rec., p. 1479) affords still another answer to the Harmatta patent and justifies a separate discussion.

It should be explained that on May 14, 1904, while the Harmatta U. S. application was pending, but before the claims for process or product were amended into it, and before the application for the Rietzel patent was filed, de Ferranti filed in the United States Patent Office an application corresponding to his Provisional application previously, to-wit, on May 25, 1903, filed by him in Great Britain. This U. S. application was afterwards divided into several divisions,

one of which, namely, that filed on the 29th day of December, 1911, was, on the 2d day of October, 1913, put into interference with the Harmatta patent.

The subject-matter of that interference consisted of broad claims 1, 2, 3 and 4 of the Harmatta patent, which, as we have seen, were copied *verbatim,* by Harmatta from the Rietzel patent, No. 928,701, being claims 1, 2, 3 and 4 of the latter patent.

For the purpose of giving the Court a clear and comprehensive idea of the fullness of the disclosure of the de Ferranti British Provisional Application, and of its application to the issues of the interference, we cannot do better than quote from the testimony of Mr. Dyer, defendant's expert, given in the interference proceeding.

Mr. Dyer testified as follows (Rec., p. 1642):

> "The de Ferranti provisional specification refers to the difficulties experienced by the patentee 'in electrically welding together the two parts which differ considerably as regards their power of rising to the required welding temperature when heated at the point of junction' (page 1, lines 6-8). It is, therefore, clear that the specification relates to an electric welding process in which the welding heat is secured by the resistance of the two pieces to be joined as distinguished from processes in which an electric arc is used. In a broad and general sense this is the so-called Thomson process originally invented and patented by Prof. Elihu Thomson about the year 1886. In the de Ferranti provisional specification the inventor refers to the desirability of so carrying the process out as to secure substantially uniform welding conditions at the point of junction when the two parts which are welded together differ considerably in mass, or in other respects differ considerably as regards their power

of rising to the required welding temperature. The specification discloses a number of ways by which the welding process may be carried into effect, some of which, in my opinion, comply with the limitations of the claims in issue herein. I have prepared and present herewith drawings illustrating the several suggestions made by de Ferranti and disclosed by him in the provisional specification. Figure 1 illustrates the suggestion that 'grooves may be cut across the edge of the ring' (lines 20 and 21). With this suggestion, assuming the invention is carried out in connection with welding a series of turbine blades to a suitable carrier, the turbine blades will be welded to projections on the carrier by a butt-welding process and not by the particular method disclosed in the claims in issue. Figure 2 discloses the arrangement suggested by de Ferranti in the statement 'or several grooves may run circumferentially completely around the edge (page 1, lines 21 and 22). In this figure I also illustrate on an enlarged scale the under face of one of the turbine blades showing the area of the several welds by section lines. These welds in Figure 2 correspond to the spots or distinct or separate spots separated from one another by well defined areas of no union as defined in the claims in issue. In other words, with the arrangement shown in Figure 2, the welds occupy only a part of the surfaces to be secured together, thus localizing the current within circumscribed paths and effecting a more rapid and economical welding operation than when the entire area of the surfaces constitute the weld. In Figure 3, I illustrate the suggestion of de Ferranti described by the words 'or, again, intersecting sets of grooves inclined to one another may be cut on the edge of the ring' (page 1, lines 22-23). In this figure I also show on an enlarged scale the underside of one of the parts (in this case a turbine blade) illustrating by sectional lines the well defined spots or areas constituting the

plurality of welds and by means of which the welding current will be localized within restricted or circumscribed areas. This particular figure is that of the de Ferranti drawing in interference and manifestly it corresponds with the restrictions and limitations of the claims. In Figure 4, I illustrate the arrangement which is described by the words 'radial holes may be bored a short distance into the edge, either arranged in patterns, so as to leave intervening projections of untouched metal to which the blades may be welded' (page 1, lines 24-26). The weld in this case corresponds substantially to Figure 1, is coextensive with the entire area of the turbine blade and does not correspond with the limitations of the issue. In Figure 5, I illustrate the arrangement disclosed in the de Ferranti provisional specification by the words 'or arranged without particular reference to the position of the blades' (page 1, lines 26-27). In this figure I show on an enlarged scale the under face of the turbine blade illustrating the area of the welds which are arranged in spots or defined areas so as to localize the heating current and this arrangement also, like those of Figures 2 and 3, corresponds to the limitations of the issue. In Figure 6, I illustrate the suggestion made in the provisional specification and described by the words, 'Again, the result aimed at may be secured by boring holes through from face to face of the ring at a radius slightly less than that of its outside edge' (page 1, lines 32-33). With this suggestion the area of the weld will correspond to the entire engaging face of the turbine blade and therefore this particular suggestion does not correspond with the limitations of the issue. In Figure 7, I illustrate the suggestion described in the provisional specification by the words 'the ring may be built up of two or more thinner rings held in their relative positions by distance pieces or in any other convenient manner, the blades being then welded in position on

their outside edges' (page 1, lines 34-37). In this figure I also illustrate on an enlarged scale the bottom face of the turbine blade illustrating by sectional lines the area of the welds which are thus located in spots or well defined areas by which the heating current will be localized. Finally, in Figure 8, I illustrate the arrangement described by de Ferranti in the provisional specification by the words 'Again, the ring may be built up of a set of laminae, the edges of which are notched, the laminea being assembled in such a way that the notches are "stepped" with regard to each other, the intervening projection of metal thus following the shape of the turbine blades to be welded to them' (page 1, line 38; page 2, line 2). Assuming that with this arrangement the laminae are arranged closely together so that the projections referred to will constitute a substantially continuous surface to which the turbine blades are electrically welded, I find that with this suggestion the weld will occupy substantially the entire area of the bottom face of the turbine blade and will not correspond to the limitations of the issue. I do find, however, that the de Ferranti provisional specification, as illustrated in Figures 2, 3, 5 and 7, suggests a method of welding electrically two pieces of metal together wherein the welds will be confined to fixed, definite, limited areas or spots, by which the heating current will be localized, and in connection with these several suggestions made by de Ferranti of spot welding the two metallic parts, which may be obviously of any suitable character, I call particular attention to the following statement made in the provisional specification:

'The object to be kept in mind in this as in other modifications, is to remove sufficient metal to enable the temperature to rise to the welding point as explained above, while at the same time leaving sufficient areas untouched to insure due me-

chanical strength in the welded joint' (page 1, lines 33-36).

From these instructions of the inventor I understand that when a process is carried out, such as disclosed in Figures 2, 3, 5 and 7 above explained, the areas of non-union are made as extensive as possible so long as the isolated or spot welds provide 'due' mechanical strength. de Ferranti does not suggest that at all times the maximum mechanical strength in the weld is to be secured, because it is obvious that if conditions are equal a weld extending over the entire area of the bottom face of the turbine blade is mechanically stronger than a weld which occurs only in isolated spots or restricted areas. The provisional specification points out that so long as 'due' mechanical strength is secured, that alone is sufficient and with this in view the areas of non-union may be as extensive as possible.

Now referring to the suggestions contained in the provisional specification and illustrated in Figures 2, 3, 5 and 7, to which I have above referred, I find that there is here disclosed a method of fastening two pieces of metal together by electrically welding them to one another at spots only of their juxtaposed or opposite faces by the application of pressure and heating current localized in such spots as defined in Claim 1 of the issue herein. Furthermore, I find that in these disclosures is suggested the method of uniting two pieces of metal at a number of distinct or separate spots separated from one another by well defined areas of no union consisting in applying pressure localized at the spots of desired union, and passing electric current through the pieces from one to the other while confining the flow of current to said spots until the union is effected, as defined in claim 2, in issue herein. Furthermore, I find that in these figures, taken from the provisional specification, is disclosed a method of

uniting two pieces of metal consisting in pressing them together while passing a heating electric current from one to the other and localizing the flow of current and the heating throughout the operation in a spot, or spots, of circumscribed or limited area as compared with the area of the immediately opposed surfaces so as to limit the union of the pieces to a spot, or spots, as defined in Claim 3 in issue herein. And, finally, I find that in these particular disclosures of the de Ferranti original specification, a method is suggested of uniting two pieces of metal at a spot or spots only in their opposed heating surfaces, consisting in pressing the two pieces together, and passing a welding electric current from one to the other, while localizing the pressure in and confining the flow of current to the spot, or spots, of desired union so as to produce an isolated spot, or spots, of union, leaving distinct or well defined areas in which the pieces are not welded together, as defined in Claim 4 in issue herein."

The declaration of this interference with de Ferranti came as a surprise to the Thomson Electric Welding Company, the then owner of the Harmatta patent, and it meant that if de Ferranti could establish priority in respect to the issues of that interference the Harmatta patent was defeated.

The owner of the Harmatta patent was indeed badly caught. It had, as we have seen, prosecuted the application for the Rietzel patent (in blissful ignorance of the existence of the then pending United States Harmatta application), procured Rietzel to swear back of the Harmatta foreign applications by asserting inventorship in 1897-8, then drawn claims for Rietzel covering completely not only his disclosure but the Harmatta foreign disclosures as well, then taken the patent in Rietzel's name, then having

acquired Harmatta, caused Rietzel to default in the interference with Harmatta, in order that judgment might be rendered against him and in favor of Harmatta, and then issued the patent to Harmatta, only, finally, to run up against an interference with de Ferranti, who claimed the right, under the law, to hark back to his prior British application of May 25, 1903, as his date of constructive reduction to practice, and thus establish priority over Harmatta, the date of whose United States application was December 3, 1903, and the established date of whose foreign application was not earlier than October, 1903:

de Ferranti v. Lindmark, 30 App. D. C. 417;
Winter & Eichberg v. Latour, 35 App. D. C. 415;
Burt v. Coats & Cameron, 47 App. D. C. 185;
Jay v. Weinberg, 250 Fed. 469-472, Sec. 4887, R. S. U. S.;
International Convention, 25 Stat. at Large, 1383.

The worst of the situation was, that, having originally drawn the claims of the issue in a case (Rietzel's) which showed only the "spot welding" through projections on one or both of the parts to be welded, the owner of the Harmatta patent was now estopped to deny the application of the claims to the similar earlier work of de Ferranti. Finding itself thus caught, the owner of the Harmatta patent entered upon a campaign of disentanglement.

It proceeded at once to move to dissolve the interference on the ground, first, that de Ferranti had no right to make the claims in issue because his original application disclosed only a process of butt welding; secondly, because the claims in issue were based upon new matter not embraced in his original application

but inserted for the first time in the divisional case in interference; and, thirdly, because he did not make the claims in issue until more than three years after the publication of the same claims in the Rietzel patent, No. 928,701, on July 20, 1909 (Rec., p. 1502).

This motion was referred to the Law Examiner for disposition and he decided that de Ferranti did have the right to make the claims in issue (Rec., p. 1528, *et seq.*). A rehearing was applied for and denied (*Ibid.*, p. 1535).

Other motions to dissolve, not necessary here to detail, were made in behalf of Harmatta and overruled, and, finally, after testimony had been taken by both sides on the question of the identity of the disclosure of the de Ferranti United States application with that of the de Ferranti British Provisional, the case was submitted to the Examiner of Interferences, who decided, first, that the invention of the issues was not found in the de Ferranti British Provisional application, and, secondly, that de Ferranti was, under the decision of the Court of Appeals of the District of Columbia, in the case of Rowntree vs. Sloan, 45 App. D. C. 207, estopped to assert the claims in issue, because they had not been made by him within a year of the date of the publication of the Rietzel patent, No. 928,701, of July 20, 1909.

On appeal to the Board of Examiners-in-Chief, the Examiner of Interferences was reversed, on the first point, and sustained on the second,—the Board holding that the disclosure of the British Provisional application of de Ferranti was sufficient to enable him to go back to it as his date of effective reduction to practice, under the Statute, but holding further that the decision in Rowntree vs. Sloan was controlling of them and required that they decide that de Fer-

ranti, by reason of his delay of about seventeen months in making the claims, was barred of his right to make them.

In their decision, on the first point, the Board said (Rec., p. 2079):

> "de Ferranti's provisional application is particularly directed to a process of attaching turbine blades. And the object of the invention is stated to be the reduction of the large amount of metal theretofore appearing in the turbine ring to which the blades are welded, so as to reduce the flow of heat from the vicinity where the blade is welded to the ring. de Ferranti described in his provisional application several different forms or processes, some of which clearly do not come within the scope of the counts. The provisional specification did not comprise a drawing.
>
> We find that de Ferranti's witness has fairly set forth the inferences which those skilled in the art would draw from this provisional application. de Ferranti's Exhibit No. 1 correctly shows, in our opinion, what those skilled in the art would understand this provisional application to describe. In making the structures of figures 2, 3, 5 or 7 of this exhibit as described in the provisional application, those skilled in the art would infringe the claims which constitute the counts of this interference.
>
> Nor can this disclosure be regarded as accidental merely because the functions and advantages thereof which underlie the invention here in controversy were not appreciated by de Ferranti. They are inherent in his process as disclosed when carried out in the manner indicated in figures 2, 3, 5 and 7 of de Ferranti's Exhibit No. 1.
>
> Nor can this disclosure be regarded as accidental merely because de Ferranti also disclosed the forms or methods indicated in figures 1, 4 and 8 of this Exhibit No. 1 which do not involve the pro-

cess here in issue. When an inventor positively and definitely describes two or more structures or processes, he is not any the less a discloser and inventor of any one of these than he would have been had he disclosed only that one.

In this connection it is noted that Harmatta's application in interference shows a somewhat similar lack of appreciation of the present invention when originally filed. The emphasis and claims therein were to the application of pressure to the weld through the electrodes though the present process was unmistakably disclosed.

We hold that the Examiner of Interferences erred in not finding the invention in controversy to be adequately disclosed in the de Ferranti provisional application."

The de Ferranti Exhibit No. 1 referred to in the above quotation is found reproduced in the record (Rec., p. 1666, *et seq.*).

On the second point, the Board of Examiners-in-Chief said (Rec., p. 2080):

"Taking up the question of estoppel we find that de Ferranti appears to have first asserted claims to the present invention on *December 6, 1910.* As Harmatta's patent did not issue until 1912 de Ferranti is not barred by the same from prevailing here. But the counts of this interference were drawn from a patent to Rietzel, No. 928,701, which issued upon July 20, 1909. Harmatta made claims to the present invention at least as early as March 31, 1910, and an interference was declared between his application and the Rietzel patent upon April 26, 1910. If de Ferranti had been claiming the present invention at that time he would presumably have been placed in that interference. It is true that the Examiner could have taken steps toward the inclusion of de Ferranti's application in that interference at any

time after December 6, 1910, when de Ferranti first laid claim to the present subject-matter. This was presumably overlooked by the Examiner. If the claims that de Ferranti advanced on December 6, 1910, had been advanced before July 20, 1910, he would not have been estopped even though the Examiner did not take steps looking to the addition of de Ferranti to the Rietzel-Harmatta interference. As it is, however, de Ferranti did not make any claim until more *than a year after* the issue of the Rietzel patent, whereas Harmatta did do so and has prevailed over Rietzel in an interference proceeding. We think that the reasons underlying the decision in Rowntree vs. Sloan, *supra*, apply to the present case and that de Ferranti is accordingly estopped to assert priority over Harmatta."

After this case was submitted to the Trial Court the interference, de Ferranti v. Harmatta, was further reviewed on appeal, first by the Commissioner of Patents, and then by the Court of Appeals of the District of Columbia.

The Commissioner held that the subject-matter in issue was not disclosed in the de Ferranti British Provisional specification and awarded priority of invention to Harmatta on that ground. The Court of Appeals, without reviewing the Commissioner's finding as to the sufficiency of the British Provisional specification, held that de Ferranti was barred and estopped from receiving a patent because he had not made the claims of the issue within two years of the grant of the Rietzel patent of July 20, 1909, in which such claims had originated; basing its decision upon the holding of this Court in Chapman & Chapman vs. Wintroath, 252 U. S., 126, which decision it construed as placing a two years' limitation upon an ap-

plicant's right to make claims instead of the one year limitation which it, the Court of Appeals, had held applicable in the same case when before it (47 App. D. C., 247) and in the previous case of Rowntree vs. Sloan, 45 App. D. C., 207.

The opinion of the Court of Appeals is reported in 50 App. D. C., 393; 273 Fed., 357.

The decision of the Court of Appeals was, in our view, wrong, for two reasons, to-wit:

(a) It assumed that this Court in Chapman vs. Wintroath had decided that a two-years' delay in making a claim after its appearance in a prior patent was fatal, whereas it did not and could not have decided any such thing, the case before it not presenting any such question. In the case before it, the applicant's delay was only about nineteen months. The Court of Appeals applying the one year rule held the delay fatal. This Court overruled this one year rule, stating that, in analogy to many of the statutory provisions permitting at least two years' grace for action by an applicant or patentee the delay of nineteen months in the case before it was justified; which was a far cry from *deciding* that in no case was a delay of more than two years permissible.

(b) The Court of Appeals overlooked the fact that de Ferranti had in fact first claimed the substance of the issues in interference not without but well within two years, if that period were the legal limitation. The Board of Examiners-in-Chief so held in their decision. (p. 162, *ante*.) That this is so will be seen from a comparison of some of the claims made in the de Ferranti parent application (of which the application in the interference was a division) with claims of the Rietzel patent constituting the counts of the interference issue:

Claims, 1, 2, 3, and 4 of Rietzel Patent No. 928,701 of *July 20, 1909*, constituting the Issues of the de Ferranti-Harmatta Interference. (Rec., p. 1101.)

1. The hereinbefore described improved method of fastening two pieces of metal together by electrically welding them to one another at spots only of their juxtaposed or opposite faces by the application of pressure and heating current localized in such spots.

2. The herein described method of uniting two pieces of metal at a number of distinct or separate spots separated from one another by well defined areas of no union, consisting in applying pressure localized at the spots of desired union, and passing electric current through the pieces from one to the other while confining the flow of current to said spots until the union is effected.

Claims made on *December 5, 1910*, in de Ferranti's parent application No. 208,034 of May 14, 1904, of which the later application of December 29, 1911, involved in de Ferranti-Harmatta interference is a division. (Rec., pp. 1267-1273.)

8. A process for uniting two parts together consisting in utilizing portions only of the individual juxtaposed surfaces for the transference of electric heating current so as to limit the heating effect of said current substantially to said portions and applying pressure so as to unite the parts by a weld of less area than that of the juxtaposed surfaces.

9. A process for uniting two parts together consisting in utilizing portions only of the individual juxtaposed surfaces for the transference of an electric current, the utilized portions being prepared so as to localize the heating effect of said current and applying pressure to unite the parts by a plurality of isolated electric welds.

3. The herein described method of uniting two pieces of metal, consisting in pressing them together while passing a heating electric current from one to the other and localizing the flow of current and the heating throughout the operation in a spot or spots of circumscribed or limited area as compared with the area of the immediately opposed surfaces so as to limit the union of the pieces to a spot or spots.

4. The improved method of uniting two pieces of metal at a spot or spots only in their opposed meeting surfaces, consisting in pressing the two pieces together, and passing a welding electric current from one to the other while localizing the pressure in and confining the flow of current to the spot or spots of desired union, so as to produce an isolated spot or spots of union, leaving distinct or well-defined areas in which the pieces are not welded together.

10. A process for uniting two parts together consisting in leading an electric current across portions only of the individual juxtaposed surfaces of the parts and applying pressure to said parts so as to integrally unite the individual juxtaposed surfaces together by a plurality of isolated electric welds.

11. A process for uniting two parts together consisting in forming projections on the individual juxtaposed surfaces of said parts, leading an electric current across the parts by way of said projections and applying pressure to unite the individual juxtaposed surfaces by a plurality of isolated electric welds.

The exact words of the Rietzel claims were not used by de Ferranti in the drafting of his claims but there

cannot be the slightest doubt of the identity of the two sets of claims in matter of substance.

The later adoption by de Ferranti of the precise phraseology of the Rietzel claims for purposes of interference with Harmatta, who had copied and adopted such claims literally, was mere compliance with technical Patent Office procedure and cannot possibly operate prejudiciously to de Ferranti in matter of essential right.

The plaintiff will doubtless contend here, as it has done in the de Ferranti-Harmatta interference, that the first four claims of the Harmatta patent are limited to a process for uniting plane-faced plates and that de Ferranti does not disclose such a process but only a process for uniting pieces one or both of which are provided with projections through which the welding takes place; but the complete answer to this is that these four claims originated in the Rietzel patent and were inserted there to cover the welding of plane-faced plates as well as the welding of plates provided with projections; were copied by Harmatta for interference with Rietzel; were adjudged to belong to Harmatta over Rietzel in such interference, and the plaintiff, now claiming under Harmatta, is estopped to deny that they include a practice like de Ferranti of welding plates or pieces having projections through which the welding takes place.

We would here remark that the question of priority of invention as between de Ferranti and Harmatta is still open, notwithstanding the judgment of the Court of Appeals of the District of Columbia, de Ferranti and his assignee having filed a bill in equity against Harmatta and his assignee in the United States District Court for the District of Massachusetts under

Section 4915, R. S. U. S., for a review of such judgment.

It is only necessary to add that the defendant here is a lawful licensee, under the de Ferranti invention and application and has *pro tanto*, a right to all the protection that the law affords de Ferranti himself (Rec., pp. 1972, 1975, 1978, 1980).

What has been said in regard to de Ferranti's priority respecting the process or method claimed for Harmatta, applies equally well to the product or article claimed by him. Both process and product are anticipated by de Ferranti.

THE BEARING OF CHAPMAN & CHAPMAN VS. WINTROATH, 252 U. S. 126, ON THE HARMATTA PATENT AS A WHOLE

If our interpretation of the decision of this Court in Chapman & Chapman vs. Wintroath (p. 164, *ante*) be wrong and plaintiff's interpretation be right, then that decision must have a profound bearing on the validity of the Harmatta patent as a whole.

That case, as we have seen, came up from the Court of Appeals in the District of Columbia on writ of certiorari. The Court of Appeals had held that the delay of Chapman & Chapman in asserting the claims in controversy after a patent containing them had been issued to their adversary Wintroath nineteen months previously, constituted such laches and abandonment as to deprive them of a right to a patent, notwithstanding the fact that their application was filed earlier than the application for the patent of Wintroath first containing the claims. This Court reversed the judgment of the Court of Appeals on the ground that according to all time analogies to be found in the

patent Statutes and the decisions of this Court thereunder, especially in reissue cases, the applicants had two years within which to assert their claims, and because their delay was less than two years they were not barred.

While in Harmatta's case there was no patent claiming the identical subject-matter issued to an adversary more than two years before he made the claims now standing in his patent, there was a public use of the process covered by those claims and of the product covered by those claims, by his assignees and licensees, in this country, for over *five* years before any of those claims were introduced into his application and there was a publication and patenting of those claimed inventions by himself in Great Britain, France and other foreign countries more than *seven* years before the making of the claims in his U. S. application. There would seem, therefore, in Harmatta's case, to be present the full equivalent of a prior patenting for over two years claimed by plaintiff to be laid down in the Chapman case as constituting fatal laches or abandonment of right.

THE PRIOR SUIT ON THE HARMATTA PATENT AGAINST BARNEY & BERRY, INC., WAS FEEBLY DEFENDED AND OUGHT NOT BE GIVEN BUT LITTLE, IF ANY, WEIGHT.

On March 13, 1913, about three months after the Harmatta patent was issued, a suit for infringement of that patent was brought in the United States District Court for the District of Massachusetts by the Thomson Electric Welding Company (as owner) and Universal Electric Welding Company (as exclusive licensee) against Barney & Berry, Inc., a Massachusetts

Corporation, which latter was using in the welding of the parts of skates, an electric welding machine built and sold by The Toledo Electric Welding Company of Ohio.

The trial of that suit came on April 1, 1914, before his Honor, Frederic Dodge, District Judge, who, on March 24, 1915, found the patent invalid and entered a decree dismissing the bill of complaint (227 Fed., 428). Appeal being taken from this decree to the United States Circuit Court of Appeals for the First Circuit, that Court, on October 5, 1915, reversed the decree of the Court below and remanded the cause for further proceedings (227 Fed., 428; Rec., p. 5). Subsequently, to-wit, on July 17, 1916, an interlocutory decree was entered on the mandate referring the cause to a master to take and state an account (Rec., p. 1982). It does not appear that any final decree was ever entered in the cause. But it does appear that the cause was settled by agreement of the parties, without an accounting (see Pamphlet of Contracts, Rec., p. 805).

Those, other than the plaintiff and its licensees, engaged in the manufacture and use of spot welding machines have never had any confidence in the Barney-Berry litigation as settling the question of the validity of the Harmatta patent. Even the plaintiff itself has shown lack of dependence upon it, for, notwithstanding the decision of the Court of Appeals sustaining the patent, no suit on the patent, other than the present one, has ever been brought on it, out of the First Circuit, and, in the present suit, the plaintiff has not had the temerity to apply for a preliminary injunction, so impressed has it evidently been with the weakness of its position.

After the decision of the Circuit Court of Appeals, over four hundred manufacturers and users of spot

welding machines located in different parts of the country and representing many millions of invested capital, banded themselves together under the name of the "Welding Patents Investigating Committee," for the purpose of gathering materials of defense against the possible aggressions of the plaintiff (see Defendant's Exhibit Bulletin No. 21, July 17, 1917, offered Rec., p. 1001).

While the defendant has made several contributions to the fund raised by this committee, they were always paid with the distinct understanding that defendant would not be thereby bound to assist in the defense of any suit brought against any other contributor, and, consistently with this determination, defendant has itself borne all the expenses of this suit and has had full and exclusive control of the same (Hartman, Rec., p. 1000).

The general distrust of and failure to yield acquiescence to the decision rendered in the Barney-Berry case has been based upon the following considerations, among others:

(1) Barney & Berry, Inc., was but a nominal defendant in that case, while the real defendant was the Toledo Electric Welding Company, and its secretary and general manager, Mr. Frank Warren, was, before and during the trial negotiating with the plaintiff a plan of settlement inconsistent with a full, wholehearted defense of the suit (McBerty, Rec., p. 802; see also Defendant's Exhibit 72, Rec., p. 2073).

Immediately after the decision of the Court of Appeals in that case the plaintiff bought out the Toledo Electric Welding Company—lock, stock and barrel—took Mr. Frank Warren into its employment, at a salary of $7,500 per annum, for three years, and agreed to give Mr. Warren additional compensation out of all

sums received thereafter by plaintiff or any subsidiary company engaged in the electric welding business, to-wit, 15 per cent of the first $50,000; 10 per cent of the second $50,000, and 5 per cent of all additional amounts received.

(2) Although the prior knowledge and use of Rietzel was well known to plaintiff and, presumably, to defendant in that case—the file wrapper of the Rietzel application for patent disclosing it—such knowledge and use was apparently deliberately suppressed and not brought to the attention of the Court in that case.

(3) Although the prior knowledge and use of McBerty set up in this case was known to plaintiff and defendant in that case, the same was likewise suppressed and not brought to the attention of the Court.

(4) Although the prior invention of de Ferranti and the existence and pendency of the Harmatta-de Ferranti interference were well known to both plaintiff and defendant in that case, the same were suppressed and not brought to the attention of the Court.

(5) Although the practicability of roller electrodes for carrying out the process was well known to plaintiff in that case and asserted by Harmatta himself, attempt was made to deceive the Court in this particular.

(6) The fact that in that case the Thomson patent No. 496,019 was attempted to be disposed of as embodying a mere process of soldering and not a welding process, although the plates described as being united by electric current and pressure were iron plates coated with tin—the only material, specifically designated anywhere by Harmatta, to-wit, in the Harmatta French patent No. 336,187, as composing the plates proposed to be united by his process.

(7) The fact that it was generally believed that Judge Dodge was right in holding that the roller-elec-

trode patent of Thomson, No. 444,928, constituted a complete anticipation of the Harmatta patent, notwithstanding his reversal on appeal as to this point by the Court of Appeals.

(8) The fact that the Lemp patent, No. 553,923, owned by the plaintiff and well known to the defendant in that case, was not set up at all, though constituting a clear anticipation of the Harmatta patent.

(9) The fact that in that case the Kleinschmidt patent was attempted to be disposed of as an anticipation of Harmatta on the basis of disclosing only the production of *big* spot welds instead of small spot welds, the plaintiff and defendant both well knowing that the size of the welds had nothing to do with the claimed process, or the claimed product of Harmatta, as established in this case.

(10) The fact that in that case the Robinson patent, No. 574,942; the Burton patent, No. 647,694; the Parkinson British patent, No. 14,536, of 1894, were entirely overlooked, or not exploited, as anticipations of the Harmatta patent.

(11) The fact that in that case the Benardos German patent No. 50,909 was not presented in its true bearing as an anticipation of the Harmatta patent.

(12) The fact that in that case the estoppel growing out of the assertion by plaintiff of the prior invention of Rietzel as a means for securing the grant of the Rietzel patent over the foreign anticipating disclosures of Harmatta and for securing to Rietzel a "look-in" in the Rietzel-Harmatta interference, was not urged against the plaintiff, though known to the defendant in that case. The Trial Court in the case at bar, was impressed with defendant's criticisms of the Barney-Berry case and so expressed itself (p. 27).

Judge Dodge's Decision

Notwithstanding the fragmentary and partial exhibition of the prior art in the Barney-Berry suit, Judge Dodge found enough in the prior patents laid before him, and particularly in the Thomson roller-electrode patent, No. 444,928, and in the Kleinschmidt patent, No. 616,436, to invalidate the Harmatta patent. Of the Thomson patent he said (227 Fed., p. 431):

> "Referring again to the Thomson patent, No. 444,928, the process therein described, while it is said to be 'especially applicable to the welding of plates together at their edges, instead of riveting,' is just as applicable to the welding of plates or sheets at other places within their area as at their edges. The roller electrodes employed, when brought together on each side of the work, and until something more is done, will pass the electrict current and make the weld at the spot or point of pressure and nowhere else. (See claim 1 of the patent referred to.) If, having then made the weld, they should be again separated, instead of having the work fed between them while their pressure upon it continued, they would leave an isolated spot weld joining the plates and be in readiness to make another weld isolated from the first by any desired area of unwelded surface.
>
> "The plaintiffs say that although machines were built to carry out the roller process of the last mentioned patent, they were not practically successful and that the process has proved a failure so far as commercial success is concerned. Their evidence tends to support this contention and to show that there are practical difficulties attending the use of the process. But so far as the question raised is important, I think the plaintiff's evidence tending to show want of success is fully met by that of the defendant; according to which the process has been successfully carried

out by machines built and commercially installed by at least two different concerns. Samples of the work they have produced by using it are among the exhibits in the case and there is nothing to show that such work is unsatisfactory in character."

Had the learned judge been fortified, further, by the admissions of plaintiff's witnesses, in this case, he would not have felt the need of even discussing the practicability of practicing the Harmatta process by means of roller electrodes.

(Gravell, Rec., p. 103, X-Q. 191; p. 104; X-Q. 199, *et seq.;* Knapp, *Ibid.*, p. 221, X-Q. 27, *et seq.;* Knapp, Jr., *Ibid.*, p. 233, X-Q. 20, *et seq.;* Clark, *Ibid.*, p. 263, X-Q. 114 *et seq.;* Thomson, Rec., p. 532, Q. 28.)

But the learned judge did not overlook the fact that Harmatta himself had asserted the entire practicability of practicing his process by means of roller electrodes, and had, in fact, described roller electrodes as the principal, and pin electrodes as the mere incidental or subordinate, means of carrying out his process.

We quote from his opinion on this point, as follows (227 Fed., p. 432):

"As has appeared, the application was pending for ten years before the patent issued.

"As originally filed the application described a process of roller welding substantially like that of Thomson, with the statement toward the close of the specification that, instead of introducing the piece to be welded gradually between the electrodes, the welding apparatus might be arranged to slide relatively to them, and that if required

to weld sheets only at particular places, apparatus employing electrodes and having the form of pins might be used, instead of the roller electrodes, to produce 'a small, round, very sharply defined place of welding,' answering the purposes of a rivet.

"There were two claims covering roller welding and two others not thus limited. The idea of roller welding thus appears to have been with Harmatta the foundation and origin of his further idea of spot welding, and his further idea to have consisted in nothing more than stopping with the first point welded instead of continuing it into a welded line."

The Decision of the Court of Appeals for the First Circuit

As compared with the well reasoned opinion of Judge Dodge, the opinion of the Court of Appeals, written by Judge Putnam, makes a poor showing.

It swallows, bait, hook and sinker, the plaintiff's contention that the roller electrode process is entirely impracticable and throws the Thomson roller electrode patent No. 444,928 and Harmatta's evidently preferred form of roller electrode apparatus disclosed in his original application and in all his foreign patents, into the discard, contrary to the weight of evidence in that case and the full admission of plaintiff in this one.

It errs in its statements as to what the record contained, indicating (what was probably the fact) that the record had never been read. It says (Rec., p. 7):

"The patent was applied for on December 3, 1903, and was not issued until December 3, 1912, *but the claim for spot welding was always in the application.*"

Now, the fact is, that of the four claims originally sworn to by Harmatta, the first two covered, respectively, a process and an appartus which entirely disregarded the form of electrodes employed or the welding in disconnected spots as distinguished from the welding in a line. They read (Rec., p. 1361):

> "1. The process of electric welding, consisting in employing the electrodes not only to conduct the current to the objects being welded, but also to exert a regulable pressure on the same, substantially as described.
>
> "2. An electrode apparatus for electric welding, comprising two electrodes between which the objects to be welded are introduced and means whereby one of the electrodes can be approached to and receded from the other, substantially as described."

The two other original claims (3 and 4) were, as we have seen, directed specifically to the roller electrode apparatus only.

The opinion of the Court of Appeals goes on further to state:

> "The alleged infringing machines were first constructed in 1908; *in 1910 the application covered both spot welding and line welding.* It was then amended by striking all claims for line welding," etc.

This was an inaccurate and untrue statement. By the amendment of May 14, 1904, everything relating to line-welding, *i. e.*, description, claims and drawings, was stricken from the Harmatta application and *never* thereafter reappeared in it!

From the whole temper of the Court of Appeals'

opinion, the impression is gained that the Court thought defendant's whole case rested upon the roller-electrode defense and that it had been shown that all roller electrode apparatus were impracticable and had been jettisoned, even by Harmatta, for that reason—contrary to what we now know and what the plaintiff's witnesses in this case admit to be the fact.

It is apparent, therefore, that, had the evidence now in this case, on this point only, been before the Court of Appeals in Massachusetts, a different result would have been reached by that Court, to say nothing of what would have been the effect of the other defenses of prior patenting, prior invention, estoppel, etc., brought forward, for the first time, in this case, had they been duly presented for the consideration of that Court.

THE PROCESS OF SPOT WELDING, SO-CALLED, OF HARMATTA IS BUT A NORMAL AND EXPECTED APPLICATION OF ELECTRIC RESISTANCE WELDING AND INVOLVES NOTHING PATENTABLE

Any one who, at any time or place, fastened two pieces of metal together by electrically welding them to one another at a spot or spots only of their juxtaposed or opposite faces by the application of pressure and heating current, localized in such spots, practiced the essentials of the, so-called, Harmatta spot welding process.

Eliminating the idea of a welding at a spot or spots comprising less than the whole of the juxtaposed surfaces of the parts to be united, we have nothing but the original Thomson butt-welding process, so-called, of 1886; but, keeping in mind and applying that idea, we

find that the process was practiced long before Harmatta, by Thomson, by Lemp, by Robinson, by Kleinschmidt, by Burton, by Perry, by de Ferranti, by Parkinson, and by still others, whose prior dates are established by record evidence; and also by Rietzel and by McBerty, whose dates are fully and satisfactorily established by the testimony offered in this case.

(a) So far as the nature of the metal parts acted upon is concerned, it matters not of what metal they are composed—they may be of any metal, as suggested by Thomson in his patents Nos. 396,015 and 444,928, by Burton in his patent No. 647,694, and by Benardos in his patent No. 50,909, or of tinned iron as suggested specifically by Thomson in his patent No. 496,019, and by Harmatta in his French patent, 336,187, or of zinc-coated metal, as in Perry, 670,808.

(b) The parts to be united may be metal in sheets of uniform thickness, as suggested in Thomson, 396,-015 and 444,928, in Burton, 647,694, and in Lemp, 553,-923, or in very thin metal sheets, as suggested in Thomson, 496,019, and in Benardos, 50,909; or thin pieces may be united to thicker pieces as suggested in Robinson, 574,942, and in Kleinschmidt, 616,436. When plates are to be united they may be plane-faced, throughout, as in Thomson, 444,928, Lemp, 553,923, and Benardos, 50,909; or they may be provided with projections on both parts, as in Rietzel, 928,701, or with projections on one part only, as in Robinson, 574,942, Kleinschmidt, 616,436, and Rietzel, 928,701. Cylindrical wires may be the material operated upon, as in Perry, 670,808.

(c) The electrodes may be of any suitable material, that is to say, copper as suggested by Burton, 647,694, and Parkinson, 14,536, or of iron, as suggested by

Thomson 496,019, or of steel, iron or copper faced with hard carbon, as in Thomson 496,019, or of graphite, prepared carbon, mixture of clay with carbon, magnesium, iridium, carbon with thin metal coatings, as suggested by Benardos, 50,909.

(d) The form of the electrodes is immaterial. They may be rollers as in Thomson, 444,928; Lemp, 553,923; and as suggested in Harmatta's original specification and in his British and French patents; they may be pin-shaped, as in Benardos, 50,909; in Burton, 647,-694; and as in Harmatta; or they may be flat, as in Rietzel, 928,701; Parkinson, 14,536; Robinson, 574,-942; and Kleinschmidt, 616,436; or concaved, as in Perry, 670,808. They may be pin-shaped and pointed as in the Harmatta patent; Benardos, 50,909; and Thomson, 496,019 (Figs. 12 and 13), or of cylindrical form and not pointed as shown in the drawings furnished with the first alleged foreign machine imported into this country (Plaintiff's Exhibit No. 8, Drawings of Machine Bought by National Co. from Silesia Co. A B C) (Rec., p. 125).

(e) It is assumed that the current must be of low voltage and large quantity, and that it is to be adapted to the electrodes used and the character of the work to be operated upon. In his original specification Harmatta gives no specific directions as to current, and in his patent, as granted after attorney's amendment, it is stated:

(Page 2, column 2 of patent specification.)

> "The time and duration of pressure and heating and the amount of pressure as well as the volume of current for effecting the weld can be readily determined by experiment for different thicknesses of metal and as well understood in the art of electric welding to which my invention relates."

While each individual worker in the art may have devised or invented some slight change or improvement in some particular part of the apparatus, the use of none of such special parts altered the essential nature of the process, as such practiced by their use for electric welding.

When, therefore, in the natural and normal development of the art of resistance welding, occasion arose to unite two flat plane-faced plates or parts of metal, at one or more spots instead of across the whole of their proximate faces, it was, we submit, but the adoption of a perfectly obvious expedient to employ relatively small electrodes for the purpose.

In proof of this, without either having knowledge of the work of any of the others, Thomson, in 1893; Rietzel, in 1897-8; Benardos, in 1889-90; McBerty, in 1901; and Harmatta, in 1903, each independently and, as we contend, without the exercise of a particle of patentable invention on his part, hit upon this same expedient.

The fact that many, operating absolutely independently, reach a result in the same way, has often been held to evidence a *lack* of invention.

Bromley Bros. Co. vs. Stewart, 51 Fed., 912-916;
Haslem vs. Pittsburgh Plate Glass Co., 68 Fed., 479-481;
National Tube Co. vs. Spang, 135 Fed., 22-29, Affd., 135 Fed., 351;
Elliott & Co. vs. Youngstown Car Mfg. Co., 181 Fed., 345-349;
Walker on Pats., 5th Ed., p. 27.

It is significant that neither of the early workers in the art referred to ever thought he had made an in-

vention when he first welded together metal plates in spots by means of pin electrodes as distinguishd from electrodes of other forms, or ever thought of applying for a patent for either the process or product resulting from the use of such pin electrodes.

Harmatta himself, although he applied for patents all over the world (see his preliminary statement, Rec., p. 1846), never originally specifically claimed, in any country, the use of such electrodes (see his British application, Rec., p. 1124; his French application, Rec., p. 1146; his Canadian application, Rec., p. 2042; and his original U. S. application, Rec., p. 1361), although he did claim roller-electrodes specifically in all of those applications.

It is also significant that Harmatta never succeeded in getting a foreign patent, even on his machine, and of course, not on his alleged process or product, in any country where an examination for novelty was made, and where patents were not granted as a matter of course.

In his own country, Germany, where a careful examination for novelty is always made, a patent was refused his assignee, William Egel (who also took the French patent No. 336,187, Rec., p. 1144). See Harmatta's Oath, p. 1364; Harmatta's preliminary statement, p. 1846; and "Patentblatt," pp. 2086 and 2092. In Canada, where an examination is also made, a patent was likewise refused. And, as we have seen, a patent was consistently refused him, for over five years, in the United States, and it was only after novelty had been accorded Rietzel (in apparent ignorance on the part of the Patent Office Examiner of the prior work of Robinson, Burton, Bernardos and others) that the Patent Office, with evident reluctance, gave him a

patent. In this connection, it should be noted that the Examiner who finally passed his case, sought to shift the responsibility for so doing upon the Examiner who had previously acted upon it. (Rec., p. 1435.)

THE ENORMOUS EXTENSION AND COMMERCIAL DEVELOPMENT OF THE ART OF ELECTRIC RESISTANCE WELDING, OR, SO-CALLED, SPOT WELDING, IS NOT ATTRIBUTABLE TO HARMATTA

In the Barney & Berry suit, it was proven that the practical art of spot welding plane-faced plates or parts together was practiced, commercially, by others before it was practiced by Harmatta or by the Thomson Electric Welding Company, and before the last-named company knew of or had acquired any rights under Harmatta's U. S. application.

In his opinion Judge Dodge said (227 Fed., p. 432):

> "Under its butt-welding patents and roller-welding patent the Thomson Company appears to have had a complete monopoly of electric welding. The latter patent expired January 20, 1908. While the monopoly continued, electric welding machines could only be had under lease from the Thomson Company, restricting their use to specified articles.
>
> In 1908 the Toledo Electric Welder Company, which made the machine which the defendant uses, and is defending this suit, began to make and introduce machines for spot welding. Other concerns followed in 1908, 1910 and 1911, all acting without knowledge of previous applications by Harmatta or others for patents covering the spot-welding process. Upon these circumstances it can hardly be said that, upon the question of patentable novelty in anything invented by him, Har-

matta is supported by any advantages which the development of spot welding since 1908 has shown to reside *in the process*, or by any commercial success it has attained. I do not think the facts shown entitle him to say that by his alleged invention, as he was finally obliged to define and limit it, he was the first to supply a widespread demand not previously met."

In the present case, we have testimony to the same effect.

Mr. Rietzel testified as follows (Rietzel, Rec., p. 638):

"Q. 35. How early was the spot welding of plane plates not provided with projections on either of their meeting faces, an established practice in the art to your knowledge?

A. I don't believe I can give any definite time and date, but I think it was three or four years after, or more, than when I made the first specimens. In fact, I only can remember of doing some commercial work, I think it was in the year 1906. There may have been some previous to that time, but I can't recall now."

Mr. Clark, a witness for the plaintiff, testified as follows (Rec., p. 261):

"X-Q. 87. You don't know who got up the design for the first spot-welding machine that was constructed or used at the Lynn factory, do you, for the Thomson Electric Welding Company?

A. I do not; it was in Mr. Rietzel's time.

X-Q. 88. And it may have been him?

A. Possibly.

X-Q. 89. When Mr. Rietzel left the Thomson Electric Welding Co. he went to the Universal Electric Welding Company, did he not?

A. Yes.

X-Q. 90. That was some time in 1907, was it not?
A. I think about that year."

McBerty, for the defendant, testified as follows (Rec., p. 742):

"Q. 198. When, to your knowledge, was a spot-welding machine for welding flat plane-surfaced plates together by pressure and current applied to one or more electrodes, first put upon the market?
A. I would say that line of product was put upon the market along about 1908. It is rather difficult for me to say.
Q. 199. What machines first appeared on the market for doing this spot-welding, so-called, and who put them out?
A. The Winfield Company manufactured the first spot-welding machine that I knew.
Q. 200. When was that?
A. That was along about that time—1908."

Gravell, a witness for the plaintiff, testified as follows (Rec., p. 70):

Answer to X-Q. 32:
" * * * The first time I came in contact with spot-welding as described by me was at the Hale & Kilburn Co., in 1910.
X-Q. 33. In 1910 was what you now call 'spot-welding,' arrived at empirically by you or did somebody communicate the idea to you?
A. While I was employed by the Hale & Kilburn Co. in the early part of January, 1910, they had already been using spot-welding for some little time.
* * * * *
X-Q. 35. Then it was from Hale & Kilburn that you first learned of spot-welding. Am I right about this?

A. That is right, but having been to the factory of the Hale & Kilburn Co. some months previous to my employment by them, I first saw spot-welding in their plant at that time."

Taylor, a witness for defendant, testified that Winfield spot-welders were sold and on the market as early as 1908 (Rec., p. 898, Q. 72).

It is not, therefore, to the invention of Harmatta, nor to the work of his assignee, the Thomson Electric Welding Company, plaintiff's predecessor, that the successful introduction and great commercial success of spot-welding, so-called, is attributable.

If Harmatta and his work had never been known in this country that development would have taken place, just the same, and, once started, could not have been stopped, any more than it can now be stopped.

With the growing scarcity of wood, the urgent demand for the use of sheet metal as a fire protection, the general availability of electric current, the expiration of the basic, dominant Thomson electric welding patents, and the appearance on the market, concurrently with these conditions, of numerous modern, up-to-date, scientifically constructed resistance welding machines, adapted especially to the convenient and expeditious welding of thin metal plates and of all sorts, kinds and shapes of small metal parts where great strength of union is not required, spot-welding, so-called, has grown apace (McBerty, Rec., p. 744; Thomson, Rec., pp. 543-544). It was not, however, until after the Harmatta patent had been sustained by the Court of Appeals that the Thomson Electric Welding Company, and later its successor, the plaintiff (composed now mainly of lawyers, Rec., p. 816) got into the field, to any appreciable extent, and using, speculatively, the

adjudication of the patent, as a club, undertook to hold up the entire commercial world and make all users of spot-welding machines pay enormous tribute, amounting now to $250 per year, for each machine.

The vigorous defense of this suit is a protest against such conduct.

There is one other thing that should be mentioned in this connection.

In the present suit, testimony has been offered by the plaintiff, tending to show that two spot-welding machines provided with pin electrodes were imported into this country from Berlin, Germany, in the forepart of the year 1905, by the National Enameling & Stamping Company, and installed at the latter's factory, at Baltimore, Md., where they have been in use ever since (Knapp, Rec., p. 124; Herring, *Ibid.*, p. 130; Knapp, *Ibid.*, p. 217; Knapp, Jr., *Ibid.*, p. 230; Herring, *Ibid.*, p. 229). These machines, though not strictly proven to have emanated from Harmatta, were said to have been procured from a German concern that purported to control Harmatta's German rights. Further evidence was offered by the plaintiff tending to show that the National Enameling & Stamping Co., using these two machines as models, caused fifteen other machines like them to be made, for its own use, and that they were so used at its different factories, all in the year 1907 (Knapp, Jr., *Ibid.*, p. 232).

Why this evidence was not availed of in the Barney-Berry suit has not been explained.

That the plaintiff knew of the existence of the machines and of their use by the National Enameling & Stamping Company is established by the fact that, on November 17, 1910, over two years before the Barney-Berry suit was instituted, the Thomson Electric Weld-

ing Company (as owner) and the Universal Electric Welding Company (as licensee) brought suit on the Rietzel patent, No. 928,701, charging the use of those very machines by the National Enameling & Stamping Company to be an infringement of the said Rietzel patent (Rec., p. 1986; Knapp, p. 227, *et seq.*), which suit was subsequently discontinued on the defendant taking a license from the plaintiff (Knapp, Rec., p. 229).

The plaintiff may have thought that the disclosure of the existence and use of these machines, in this country, as early as 1905 would show a public use for profit more than two years prior to the making of either the process or product claims of the Harmatta patent, and thus raise an uncomfortable bar, difficult to handle; but, whatever the plaintiff's motive may have been, the fact remains that the introduction of the machines from abroad and their duplication, subsequently, does not enable the plaintiff in this case to truthfully say that the great commercial extension of resistance or spot-welding was attributable, directly or indirectly, to the work of Harmatta, or his assignees. The use by the National Enameling & Stamping Company appears to have been confined to its own factories.

SPOT WELDING BY McBERTY IN 1901

It appears that, in the early days, every one who first began to use an electric resistance welding machine for the, so-called, butt-welding of metal bars or plates, end to end, sooner or later, and naturally, drifted into its use for the welding of plates or bars, flatwise, face to face. The use, for one purpose, seems to have suggested the other. Each operator appar-

ently reasoned that if he could weld the ends of plates together, he could also weld their side faces, or as much of such faces as he desired, together.

Thomson, Lemp, Rietzel, Robinson, Kleinschmidt, Burton, Benardos, and others all caught this idea and proceeded, by the use of slightly differing forms of apparatus, to apply it. Another to do the same thing was Mr. Fred P. McBerty, of Warren, Ohio.

The history of his work occupies a considerable portion of the record. There can be no doubt whatever that he repeatedly spot welded according to the, so-called, Harmatta process, as early as 1901,—before the earliest work of Harmatta—and the principal controversy, as to him, has been as to the *amount* of work that he did at that time. We may say, however, in passing, that if he practiced the invention, at all, even in a single instance, and disclosed it to others so that they could and did also practice it, he, under the authorities, completely anticipated Harmatta.

Egbert vs. Lipman, 104 U. S. 333;
Coffin vs. Ogden, 18 Wall. 120;
Brush vs. Condit, 132 U. S. 39;
U. S. Mineral Wool Co. vs. Manville Covering Co., 125 Fed. 770.

Mr. McBerty was, at the critical period, a mechanical engineer and little versed in the science of electricity. From 1898 until 1902 he was the superintendent of the plant of the Warren Electric & Specialty Company, of Warren, Ohio, a concern that manufactured and sold incandescent lamps, transformers, desk fans and ceiling motor fans. Up to 1901, the Company made desk fans in which the spiders, the fan blades and guard wires were all composed of brass,

the blades,—four in number,—of each fan being connected to a corresponding number of arms of the fan spider by means of rivets, applied in the usual manner. The guard wires of these fans were secured at their abutting ends in a variety of ways, as, for example, by slipping a metal sleeve over both ends of the wires and soldering the parts in position; or by milling or reducing the ends of the wires and lapping them, and then pinning them together, completing the joint by solder; or by drilling a hole in the end of each wire, slipping a pin in the holes thus formed, to hold the ends in alignment, and then soldering the joints. Fans of this description are shown in the 1900 Catalogue issued by the company of which a copy is in evidence (See Defendant's Exhibit No. 1, 1900 Catalogue of the Warren Electric & Specialty Company," offered Rec., p. 674.)

In the latter part of 1900, the Company concluded to add to its output a cheap grade of fan which should sell for a price less than that charged for its other fans, and it was determined that these cheap fans should have the fan blades, spiders and guards constructed of steel. Mr. McBerty had read some descriptions of the construction and operation of Thomson butt welders, and, supplementing this knowledge with information derived from Mr. Edward B. Craft, an electrical engineer employed by the Company, he designed and had built an electric welding machine, with a view, primarily, to butt-welding together the ends of the steel guard wires that were to enter into the construction of the new fans. This welding machine was the first that had ever been installed at the factory and, in fact, the first one that Mr. McBerty had ever actually seen. It fulfilled its original pur-

pose admirably. The witnesses on both sides agree that steel guard wires were successfully welded by means of it in 1901 (McBerty, Rec., p. 715, *et seq.*). Little, Rec., p. 311; Spade, *Ibid.*, p. 314; L. C. Brewer, *Ibid.*, p. 271, *et seq.*; C. R. Brewer, *Ibid.*, p. 285; Wolfe, *Ibid.*, p. 249.

With this, to him, perfectly novel electric welding apparatus to play with, it was inevitable that, sooner or later, Mr. McBerty should, like previous users of butt-welders, come to the welding of metal plates, face to face. As a matter of fact, after accidentally discovering that he could weld pieces of sheet steel scrap together, it occurred to him that he could weld his steel fan blades to his steel spider arms by applying pressure and current to them, at spots, and thus form a union that would answer the purpose of rivets. Just how this came about is best told in his own language (Rec., p. 716):

"Q. 45. And after you had successfully welded the ends of the guard wires on this steel-bladed fan, how came you to arrive at the conclusion you could also weld the fan blades and spiders?

A. That was the result of an effort on my part to electrically weld copper wire of a reasonable cross section, approximately the same cross section as the guard wires.

* * * * *

Q. 47. You mean to butt weld them?

A. Yes, sir.

Q. 48. You may go on with your illustration.

A. When I tried this operation, I was not successful in making a weld; I did not seem to get the heat necessary to fuse the projecting ends. This led me to believe I did not have sufficient resistance at the point of contact between the abutting ends of the copper wire, but I did know that this

resistance was generated by heat on the iron wires; to get, therefore, practically the same effect on the two copper wires, as I did get on the two iron wires, I put pieces of sheet steel, small pieces of sheet steel, between the abutting ends of the copper wire; the copper wires were clamped in position in the jaws; small pieces of steel placed between the abutting ends, pressure applied; with the aid of the lower clamp to move the swinging plates toward each other, and turn on the current, and while I generated heat, apparently lots of it, I did not weld my copper wires, *but I did weld my two steel plates.*

Q. 49. How did you expect to weld the two copper wires with the steel plates interposed between them?

A. My impression was that the resistance of the the steel plates would generate sufficient heat which would be communicated to the copper wires to bring them up to the fusing point, and the pressure applied would force out the steel plates which would melt up, and I would have a weld.

Q. 50. You mean you expected the copper wires would pass through the steel plate after a proper degree of heat?

A. Yes, sir; after a proper degree of heat, or they would burn up or melt out the steel plates.

Q. 51. So that the ends of the copper wires would come in contact?

A. Yes, sir; the ends of the copper wires would come in contact.

Q. 52. And be sufficiently heated to weld?

A. Yes, sir.

Q. 53. Tell us again what the result of that trial was.

A. The steel plates came up to a welding heat on their two meeting surfaces, but my copper electrodes did not come up to a welding heat, when I cut the current off. Since that experiment was not successful, I found I had made a perfect weld between the two steel plates.

Q. 54. Now, how did you utilize that discovery, if at all?

A. After repeated experiments, or repeated demonstrations, of the process to enable me to get a good idea of the strength of a union of that kind, it appeared to me that could be used to replace or to take the place of the rivets in the steel blade guards or centers.'"*

Following up this discovery as to what could be done in the way of uniting two plates, face to face, by his electric welder, Mr. McBerty proceeded to slightly modify his machine so as to conveniently weld the steel fan blades of his new fan to the steel spiders or centers. This modification consisted in inserting and holding in the clamps originally designed to hold the ends of the steel guard wires, a pair of co-operating copper electrodes, and, by first clamping the fan blades and spider arms to be united between these electrodes and then turning on the current, a weld was made at the point of application, answering the purpose of a rivet (Rec., pp. 717 and 721). The number of welds formed was, of course, determined by the number of applications of pressure and current to the work, through the instrumentality of the electrodes, in the manner described.

*It is a curious coincidence that what Mr. McBerty tried to do, *i. e.*, burn through steel plates so as to bring the copper electrodes together, but did not succeed in doing, Mr. Gravell, plaintiff's expert witness, succeeded, though inadvertently, in doing, in admirable fashion, at the test made by him at Detroit in the presence of his Honor, Judge Killits. Mr. Gravell on that occasion walked up to a perfectly new, modern, up-to-date spot welding machine, and, placing two large, clean, superposed steel plates between the electrodes, applied to the plates pressure and current long enough to burn a hole clear through the plates (see "Plaintiff's Exhibit 26, Large Sample of Spot Welding," Rec., p. 268), so that the electrodes came in contact with each other! Mr. McBerty apparently had not sufficient current, while Mr. Gravell used too much.

When Mr. McBerty had demonstrated the feasibility of uniting the fan blades of this cheap fan to the spider arms, by welding, his project was so well thought of that he made up fifteen or sixteen fans in this way, put them through the usual tests, common to other fans, and they were then disposed of as a part of the regular output of the factory. Furthermore, in getting up the Company's catalogue for the season of 1901, a cut was made of this cheap fan and the same was designated as the G-2 fan and referred to as an "ironclad" fan. When, however, it came to discussing the subjects of actually putting out this cheap fan, in quantities, it was decided that the former practice of riveting the fan blades to the spiders should be continued, first, because the Company had all the appliances for punching the rivet holes in the parts and for applying the rivets; secondly, because the workmen were familiar with such old methods of attachment; thirdly, because more welders and jigs would have to be built if welding were adopted, one welder not being sufficient to do all the work required; fourthly, because it would involve the carrying of double stock, namely, blades and centers adapted for riveting and other blades and centers adapted for welding. Another consideration that probably had some weight with Mr. Gilmer, the General Manager, was that the broad generic art patent of Thomson was still in force and covered all applications of resistance welding and to continue to spot-weld the fan blades would be to invite a law suit. Notwithstanding the very limited quantity of spot welded fans that were put out during the season of 1901, they were not only advertised and shown in the Company's catalogue of 1901, as "Ironclad" G-2 fans, but were likewise advertised, as thus

shown, in a trade journal, called the "American Electrician," in the issue of April, 1901, page 163 (Rec., p. 772), and continued to occupy a place in the advertised output of the Company contained in the Company's catalogue for 1902 (Rec., p. 728).

Quite a number of reliable witnesses testify to the building of the welder in 1901 and to its use during that year, both for the *butt welding* of the steel guard wires of the G-2 fans, and for the *spot welding* of the fan blades to the spiders. We give below brief references to the testimony of these witnesses.

Fred P. McBerty

Mr. McBerty testifies in detail to the construction of the welder and its use for butt welding (Rec., p. 715), also to the modification of the machine for spot welding and to the manner in which spot welding of the fan blades to the spiders took place (*Ibid.*, p. 717, *et seq.*). He says the spot welded fan blades were tested and found to be satisfactorily united to their spider arms, and he gives the details as to the manner in which the welds were tested (*Ibid.*, p. 723). He tells us that the spot welding of the blades was regarded as a realization of the directions given him to produce a cheap fan (*Ibid.*, p. 724). He tells of the making of the cuts of the spot welded fan for the 1901 Catalogue (*Ibid.*, p. 724). He points out that, whereas all of the other fans shown in the 1901 Catalogue disclose the fact that the blades are riveted, the cut of the G-2 fan shows no rivets (*Ibid.*, p. 725). He says that fifteen or sixteen of the G-2 fans were shipped out and disposed of as regular product (*Ibid.*, p. 726). He explains in detail the discussion between himself, Mr. D. W. Gilmer, the general manager, and Mr. Jasper

Powers, and the arguments advanced why the ordinary method of riveting should not be displaced by spot welding, as follows (*Ibid.*, p. 727):

"Q. 107. Why, if you know, were not more of this type of fan with the spot-welded blades and spiders put out?

A. That was a matter that was discussed between D. W. Gilmer, the general manager of the Warren Electric & Specialty Company; Mr. Jasper Powers, the production man, or machine shop superintendent, of the Warren Electric & Specialty Company; and myself. We had to get out a certain number of fans in a given time. We got our sample fan completed, and the matter of spot welding the blades was taken up with Mr. Gilmer and with Mr. Powers, Powers being the mechanical man, having in charge the production of the metal parts of the fan, and he rather insisted that we stick to the older method of riveting, due to the fact that he had the punches made for punching his centers, and punching his blades. He had operators skilled in putting these blades in position, and could go through all the regular processes without any interference at all, it was standard, whereas, if they had to be spot welded, it meant an electric welding machine with capacity enough to take care of our current for welding both the blades and spiders and required considerable time, particularly if we got what we call a hot season, and be compelled to produce a lot of fans, and again, he would have to purchase jigs for holding the blades in position, and also another welding machine, to give us capacity to take care of the product. All those would involve an outlay of considerable money, which was quite an object with us, and the delay, due to the production of the additional machine, jigs, and furthermore, it would compel us to carry a line of fan blades which were punched ready for the

> brass rivets, a line of centers already punched, and a line of blades not punched, and a line of centers not punched, thus compelling us to carry duplicate stock, which we always avoid if we can. The final result was they overruled my spot-welding idea, sticking to the riveting for that season, with the definite understanding if anybody wanted spot-welded blades we would be in a position to weld them."

He explains the perpetuation of the cut of the G-2 fan in the catalogue of 1902, and that the G-2 fan of that catalogue is the only one which does not show the blades riveted to the spider arms (*Ibid.*, p. 728). He points out, further, that the guard rings of the G-2 fans illustrated in the 1902 Catalogue show no joint, thus indicating that they were electrically welded (*Ibid.*, p. 729). He explains that the 1903 and 1904 catalogues issued by the Peerless Electric Company—that succeeded to the fan business of the Warren Electric & Specialty Company—omit the illustration of the G-2 fan shown in the 1901 and 1902 catalogues, indicating that all of the fans put out during those years had the blades riveted (*Ibid.*, p. 730). He explains the diligent efforts that he has made to recover one of the spot welded G-2 fans put out in 1901, showing that most careful investigation had been made through searchers sent to different parts of the country and through elaborate schemes of advertising (*Ibid.*, p. 731). He states where the transformer was obtained that was used in connection with the welder, and names a number of witnesses who were familiar with his spot welding practice in 1901, including in the list, Captain William E. Smith, Mr. McDonold, the motor tester, and Mr. E. B. Craft, the electrical engineer, now connected with the Western Electric Company (*Ibid.*, p. 732).

He says that Jasper Powers was the man who built the welding machine under his direction (*Ibid.*, p. 732). He produces a specimen of work done by him in 1901, consisting of a spider arm and fan blade spot welded together, the same being marked "Defendant's Exhibit M" (*Ibid.*, p. 737). This was one of the first satisfactory specimens of spot welding that he made (*Ibid.*, p. 735). It bears a date mark, "2-15-01," which he says means Feb. 15, 1901, and was applied by him to the specimen on that date (*Ibid.*, p. 736). It also bears the impression of a stamp reading "F. McBerty," which he says was applied at the same time (*Ibid.*, p. 737). The stamp itself is offered in evidence as "Defendant's Exhibit L" (*Ibid.*, p. 737). He says this specimen "Exhibit M" originally formed part of a center or spider having two spot welded blades attached, and that when his company, the National Electric Welder Company, was threatened with suit under the Harmatta and Rietzel patents in December, 1912, he cut the center in two, retaining the part which now constitutes "Exhibit M" and sending the other part embracing a part of the center and one blade spot-welded thereto, to his attorney, J. Nota McGill, of Washington, D. C., (*Ibid.*, p. 739). He produces a letter dated January 29, 1913, in which Mr. McGill asks him to send him one of the fan blades which was spot welded in 1901 (*Ibid.*, p. 756), and a copy of his letter in reply, dated February 1, 1913, announcing the sending of the fan blade to Mr. McGill, by parcels post (*Ibid.*, p. 756). He also produces a letter from Mr. McGill, dated February 3, 1913, acknowledging receipt of the fan blade (*Ibid.*, p. 757), and another letter from Mr. McGill to the National Electric Welder Company, dated Sept. 2, 1913, stating that he was turning over

the fan blade to Mr. Edwards, the attorney for the Toledo Electric Welder Company, who was conducting defense of the Barney-Berry suit (*Ibid.*, p. 762), also a letter from Mr. McBerty to Edwards, Sager & Wooster, dated January 20, 1917, calling for the return of the fan blades (*Ibid.*, p. 757), and the reply of Messrs. Edwards, Sager & Wooster, acknowledging the receipt of the letter last referred to and stating that the sample blade had been turned over to and had become the property of the plaintiff, the Thomson Spot Welder Company (*Ibid.*, p. 758).

He produced the original welding machine (Defendant's Exhibit B), built in 1901, and explained what parts of it are originals and what reproductions (*Ibid.*, p. 767, *et seq.*, p. 817, *et seq.*) He operated the machine in the presence of His Honor, Judge Killits, at the defendant's plant, in Detroit, producing with it (1) Defendant's Exhibit No. 56, consisting of a complete set of steel fan blades, spot-welded to a steel spider or center; (2) Defendant's Exhibit No. 57, consisting of two steel plates one-sixteenth of an inch thick, spot-welded together at a number of places, constituting a succession of welds, beginning near the middle of the sheets and extending to the edge and then extending inwardly again to the opposite edge (*Ibid.*, p. 769); and (3) another specimen, marked Defendant's Exhibit No. 58, consisting of two plates of one-eighth inch steel stock one and one-half inches wide, spot-welded together in three places (*Ibid.*, p. 769).

He also, with the same machine, produced a number of samples of butt-welded wires, marked, respectively, Defendant's Exhibits Nos. 59, 60 and 61.

During the examination of Mr. McBerty, it was developed that, in the year 1911, the National Electric

Welder Company, of which he was an officer and part owner, was organized to manufacture electric welding machines for both butt and spot welding. Other companies, such as the Winfield Electric Welding Company and the Toledo Electric Welding Co., were at that time engaged in the manufacture and sale of the same kind of machines. After the National Company got started, it was notified by the Thomson Electric Welding Co., the predecessor of the plaintiff, that in the putting out of spot-welding machines, it was infringing upon the Rietzel patent owned by the Thomson Company and also upon the Harmatta patent (Rec., pp. 738 and 745).

The Rietzel patent had been issued on July 20, 1909; the Harmatta patent on December 3, 1912, both to the Thomson Company. The formal notice of infringement was received some time in December, 1912; but, before that time, having learned that the Thomson Company had brought suit against other users of spot-welding machines, under the Rietzel patent, Mr. McBerty had consulted with Mr. J. Nota McGill, of Washington, D. C., his patent counsel, as to how his company could best get protection against the claims of the Thomson Company by reason of his prior work in 1901.

Mr. McBerty showed Mr. McGill the specimen of spot-welding produced by him in 1901 and the welding machine by which the work was done at that time, and the question was canvassed as to how safe it would be to submit the original specimen to the Thomson Company if negotiations looking to immunity from suit were opened up with the Thomson Company (*Ibid.*, p. 739); and the suggestion was made by Mr. McGill that the specimen should be cut in two and a part only used in the negotiations, the identified part

or section (Defendant's Exhibit M, bearing the date 15-2-01) being retained in Mr. McBerty's custody (*Ibid.*, p. 739). This interview with Mr. McGill occurred at Warren, Ohio. Mr. McGill did not take away any part of the specimen with him at that time, but, having meantime arranged for a meeting with Mr. F. P. Fish, counsel for the Thomson Company, he on January 29, 1913, wrote to the National Company to send him a specimen of the welding, saying (*Ibid.*, p. 931):

> "I have asked Mr. Fish to designate some day next week when I may see him in New York.
>
> Please send me one of the fan blades which was spot-welded in 1901, or thereabouts. I mean one of the two which Mr. McBerty showed me when last in Warren. Let him mark it in some way so that he can hereafter identify it when returned."

To this letter, the National Company, through its assistant secretary, replied, under date of February 1, 1913 (*Ibid.*, p. 756):

> "Re your letter of January 29, 1913. We forwarded you today, by parcel post (registered) the fan blade which was spot-welded in 1901 or thereabouts.
>
> We could not give this more prompt attention due to the fact that Mr. McBerty was out of the city, and the writer could not get into the box in which he keeps his valuables."

The specimen blade that was thus forwarded, Mr. McBerty says was stamped by him, before forwarding, in accordance with Mr. McGill's suggestion, with the same private stamp punch "F. McBerty" that had been previously used to stamp Exhibit M (*Ibid.*, pp. 763-764).

The receipt of the blade was acknowledged by Mr. McGill in a letter dated February 3, 1913, which says (*Ibid.*, p. 757):

> "I have your letter of the 1st instant and also the blade welded in 1901. Mr. Fish advises me that he may be able to make an appointment for some day next week."

Mr. McBerty says an interview at Boston with Mr. Fish and others connected with the Thomson Company, was arranged at which he (McBerty) was present and that, on that occasion, he showed Mr. Fish the other cut-off portion of Exhibit M, though he did not leave it with him.

Mr. McBerty further says that after hearing his story, Mr. Fish told him he thought his early work only amounted to an abandoned experiment, and that he (McBerty) then returned the sample to Mr. McGill, who later turned it over to Mr. Edwards, the attorney for the Toledo Electric Co. That the specimen blade was turned over to Mr. Edwards is shown by a letter from Mr. McGill to the National Co., dated September 5, 1913, which says (*Ibid.*, p. 762):

> "I have had an extended interview with Mr. Edwards, the attorney for the Toledo Company, and have turned over to him the several notes of introduction of use witnesses and copies of their affidavits *and the specimen fan blade.*"

Receipt of this fan blade was acknowledged by Mr. Edwards in a letter to Mr. McBerty, dated September 20, 1913, stating (*Ibid.*, p. 763):

> "We have received from Mr. McGill the *data* regarding the early use of spot-welding by the

Warren Company. We would like to send Mr. Howe, of this office, to interview yourself and the other witnesses of this use in order to put the matter in the shape of affidavits, and also to investigate any collateral evidence that might be developed in order to corroborate the various witnesses.'"*

Mr. McBerty testifies that in January, 1917, before the commencement of this suit, he wrote Mr. Edwards for the return of the sample fan blade, to which letter he received a reply reading as follows (*Ibid.*, p. 758):

"Dear Sir:

"Replying to your letter of inquiry regarding the sample of fan blade and affidavit, we beg to say that we examined this matter very carefully at the time it was presented and did not press the point of the exclusion of the evidence by Judge Dodge because, in our opinion, it would have been ineffective against the Harmatta patent. We considered that it would have been regarded by the court as an abandoned experiment. We understand that the National Electric Welding Company, as well as practically all other makers of welding machinery in the United States, is now licensed under the Harmatta patent, and, in view of the fact that the preparation of the affidavit was entirely paid for by the Toledo Company, and in view of the fact that the assets of the To-

*Among these data Mr. Edwards, when called by the plaintiff, admits was the sample fan blade delivered to him by Mr. McGill (Rec., p. 291).

Mr. Howe, plaintiff's witness, does not say that any of the samples annexed to the McBerty affidavit produced by him is the sample fan blade left with Mr. Edwards by Mr. McGill, nor that any of those samples were turned over to him by Mr. Edwards. Mr. McBerty, however, testifies positively that the sample delivered by him to Mr. McGill is not among the samples annexed to the affidavit (Rec., p. 886, Re-D. Q. 1209). The conclusion to be drawn, therefore, is that the missing sample which fits the sample of blade and center (Exhibit M) produced in evidence by Mr. McBerty, is still in plaintiff's possession and has been withheld. (*Ibid.*, p. 758.)

ledo Company have been transferred to the Thomson Spot Welder Company, the affidavit and sample are now the property of the Thomson Spot Welder Company and cannot be delivered without an order from that company. Will you, therefore, take the matter up directly with the Thomson Company?

Yours very truly,

EDWARDS, SAGER & RICHMOND."

From all this evidence it is clear that the missing mating-piece that was cut from Exhibit M is still in the possession of the plaintiff, and that its production in evidence has probably been withheld because of the corroboration it would afford of Mr. McBerty's story in regard to the matter.

Major Edward B. Craft

Major Craft is an electrical engineer. At the time of giving his testimony in this case he was assistant chief engineer of the Western Electric Company, in New York City, with about two thousand (2,000) engineers under him (Rec., p. 773), and had recently returned from war work abroad in the Radio Department of the United States Navy, having been over there on the staff of Admiral Sims.

He was employed by the Warren Electric & Specialty Company, at Warren, off and on, between 1898 and until the first of 1902 (*Ibid.*, p. 774). He went with the Western Electric Company, January 6, 1902, and has been with that company ever since.

He testifies that he got his first experience in electric welding at a visit made to the works of the Pneumatic Wheel Company, Freehold, New Jersey, which Company had purchased of the Warren Electric & Specialty Co., a welding transformer (*Ibid.*, p. 774). Says

that in the latter part of 1900, when the Warren Company was considering the development of a cheap fan with parts of steel instead of brass, the conclusion was reached by him and McBerty of the possibility of utilizing electric welding in the production of the new fan. Accordingly, a rather crude welder was built adapted primarily to the butt-welding of the ends of the steel guard wires of the fan. This welder worked successfully for that purpose (p. 775). He says Mr. McBerty at that time also spot welded some of the steel fan blades of that fan to the steel spiders. He did not actually see Mr. McBerty do this spot welding work, though he remembers that McBerty showed him some of the spot welded fans and satisfactorily demonstrated the strength of the union between fan blades and spiders to him (p. 775). He saw incomplete and wholly completed fans with spot welded blades at that time (p. 775) and saw the fans in operation, running (p. 790). The spot welds served the place of rivets (p. 776). The steel spiders employed were of regular stock and perforated, but the blades welded to them were unperforated (p. 776). For the spot welding of the fan blades pointed copper electrodes were provided (p. 777). He saw the McBerty machine when demonstrated to Judge Killits at the Ford plant and identified it (p. 777). The spot welded work done on this occasion was similar to that seen by him in 1901 (p. 778). He doesn't remember the exact number of completed spot welded fans that he saw at Warren in 1901, but thinks there were at least half a dozen (p. 780). Some of the spot welded fans that he saw were ready to ship (p. 790).

He remembers personally trying to weld fan guards, but doesn't recall trying to weld anything else (p. 792).

The testimony of Major Craft is important because of his standing and his entire disinterestedness.

Jasper W. Powers

Mr. Powers is now in charge of tools and production at the great machine shop of the Babcock & Wilcox Company, at Barberton, Ohio. (Rec., p. 873.)

He was engaged as a machinist and toolmaker at the works of the Warren Electric & Specialty Company between 1898 and some time in 1902, when he went with the Peerless Electric Company and worked in the same capacity till May, 1903 (p. 873).

While with the Warren Electric & Specialty Co., he, under the instruction of Mr. McBerty, built an electric welder for the welding of the iron guards of a cheap fan they were then getting up. This was in the early months of 1901 (p. 874). He identifies the welder, Defendant's Exhibit B, McBerty Machine, and points out parts he remembers working on (p. 874); says he himself operated the welder and welded on it a set of rings which he sent to his brother, who was a magician "doing magic work" at the Pan-American Exposition, at Buffalo, in 1901; that he filed up this set of rings and had them nickel-plated for use at the Exposition (p. 875).

He sent the rings to his brother in April or May, 1901, and himself attended the exposition in July, 1901. He remembers his brother saying, when about to give a performance, "Gentlemen, you will closely observe these rings are not made in a blacksmith shop; these are electric welded" (p. 875).

He testifies he also saw spot welding done on the McBerty welding machine (p. 875). He doesn't recall seeing completed spot welded fans, but remembers

seeing pieces of fan blade stock and pieces of transformer iron spot-welded together and that the welds were good and strong and could not be broken (p. 876). The welds served the place of rivets (p. 876).

Mr. Powers gives his recollection of the reason why spot welding was not generally adopted for the production of the cheap fans, as follows (p. 877):

> "Q. 52. Do you know why the spot welding was not adopted as a general manufacturing proposition for this cheap fan?
>
> A. Not entirely, no.
>
> Q. Tell the Court what, if anything, you know about that.
>
> A. Your honor, I had built up and made a complete line of tools for riveting blades, for riveting spiders, and the men were trained for doing the work in that way; and while I was responsible for the production, for whatever fans we built, that is, the mechanical work on whatever fans were built, I rather argued in favor of continuing the riveting. The season was coming on, as I remember, and we had everything required to continue the manufacture of fans, or proceed with the manufacture of fans, by riveting.
>
> Q. 54. You mean that you argued; with whom did you argue about that?
>
> A. Our manager, Mr. Gillmer, and Mr. McBerty, who, as I remember, rather favored, did favor, welding of the iron blades to the spiders.
>
> Q. 55. Then, at that time Mr. McBerty spot welded the blades to the spiders, you and Mr. Gilmer and Mr. McBerty discussed its regular manufacture by the company?
>
> A. Yes, sir.
>
> Q. 56. And you objected to it for the reasons you stated?
>
> A. Yes, sir.
>
> Q. 57. And they favored it?

A. Well, Mr. Gillmer did, and we proceeded to make them that way, by riveting.

Q. 58. How were the rivets headed up, at that time, by hand or machine.

A. They were what we called hand riveted."

Mr. Powers says the only spot welding machine he ever saw was that made and used by Mr. McBerty in 1901 (p. 878). On his recall (*Ibid.*, p. 982) Mr. Powers says he made the electrodes that were used by Mr. McBerty for spot welding; that they were of hard drawn copper wire and had pointed or conical ends, and that they were made before the conference between Mr. McBerty, Mr. Gillmer, and himself, when the subject of using spot welding as a manufacturing process, for the season, was discussed (p. 982).

John S. Gilder

Mr. Gilder went to work for the Warren Electric & Specialty Company in 1900, and worked in the fan department (Rec., p. 902). He says that at that time the fan blades put out by the company were made of brass and the spiders of bronze; that in 1901 pressed steel blades, iron spiders and steel guards were employed in the construction of cheap fans known as G' and G² fans (pp. 902-903). The fan guards or rings of these fans were welded by an electric welding machine, which he himself at times operated (p. 903). He identifies the machine, Defendant's Exhibit B, as the one used by him in 1901 (p. 903). Says he saw some fan blades for this cheap steel bladed fan that had been electrically welded to their hubs or spiders. Does not know how many, but a tray full containing eight or ten or a dozen. Examined these fan blades and saw they were spot welded;

the welds taking the place of rivets (p. 904). He didn't see any one do the spot welding. The advent of the electric welder caused a good deal of talk among the shop hands. This welding of the fan blades was done the first year the cheap steel fans were made (p. 905).

Evrah C. Lipps

Mr. Lipps is at present foreman of the tool room of the Packard Motor Car Company, at Detroit, Michigan (Rec., p. 916). He was employed by the Warren Electric & Specialty Company, in 1900 and 1901, leaving such employment in June, 1901 (p. 916). He remembers an electric welding machine that was used in the Warren Company's shops in 1901. He occasionally used it himself to butt-weld rings together, though that was not his regular duty (p. 916). He remembers that other things were welded on the welding machine (p. 916). Knows that steel fan blades were welded to the center member (p. 917). He doesn't recollect seeing the actual welding of these fan blades, but recalls seeing them after they were welded (p. 917). On being shown the old welder he identified it as the machine he saw in the factory of the Warren Electric & Specialty Manufacturing Company, before he left there in June, 1901 (p. 917).

The fan blades that he saw were completed fan blades (p. 917). He assisted in making the welder (p. 918). Others who participated in that work were Mr. McBerty and Jasper Powers (p. 918). He remembers that Mr. E. B. Craft was at the factory of the Warren Company while he was there (p. 924). He recalls that bent electrodes were at one time used in the machine (p. 923).*

*NOTE: To this day bent electrodes are sometimes used for spot welding where the work cannot well be passed between the electrode holders. (See Electric Welding, by Hamilton and Oldberg, p. 103.)

On cross-examination, Mr. Lipps was shown an affidavit executed by him in 1913, for use in the Barney-Berry suit, and he testified that the facts set forth in that affidavit were true, according to his recollection at the time the affidavit was made. The affidavit will be found printed in full in the record (Rec., p. 450).

Mr. Lipps was forty-five years old when he made the affidavit and fifty-one when he gave his testimony in this case. Attached to his affidavit and marked "Exhibit "H" are two thin metal plates or sheets that were spot welded together by him in 1901. He had not seen these plates since he gave his affidavit, but was able to identify them (Rec., p. 922). Up to the time of giving the affidavit this spot-welded work had remained continuously in his possession (Rec., p. 453).

In the affidavit, he said that in 1901, at the factory of the Warren Electric & Specialty Company, he saw steel fan blades welded to the steel hub arms in a number of distinct spots and saw others that had been previously so welded. He also said that, so far as he knew, the spot welding of fan blades to the centers was not adopted commercially (Rec., p. 454). In his affidavit, Mr. Lipps refers to the affidavit of Mr. Frank G. Brown (*Ibid.*, p. 478) and to the specimen of spot-welded work attached thereto, marked "Exhibit B," consisting of a fan blade spot-welded to a spider arm and identifies that specimen as identical with what he saw in 1901, if it is not indeed one of the very things he saw (*Ibid.*, p. 454). The Court is asked to read the whole of the Lipps affidavit and also that of Frank G. Brown (*Ibid.*, p. 478). Brown, being dead, could not be examined.

John A. McDonald

Mr. McDonald is at present employed by the Trumbull Public Service Company, at Warren, Ohio, in

electrical construction work (Rec., p. 878). He testifies that from 1898 to 1911 he worked first for the Warren Electric & Specialty Company and then for the Peerless Electric Company.

When he went with the Warren Electric & Specialty Company, all the fan blades and spiders put out by the company were made of brass (p. 879). At first the centers or spiders were provided with three rivets; afterwards with two rivets (p. 879). The fans were, at first, made all of brass and then, for the construction of a cheap fan, they were made of steel (p. 879). The guards of the cheap fans were made of iron and their ends were welded together in an electric welding machine (p. 879). He saw some of this work done and did some himself (p. 880).

First saw the welding machine in the early spring of 1901—February or March (p. 880).

The cheap fan was known as the G^2 fan—G^2 and G^1 (p. 879). He was shown and identified the company's catalogue for 1901 (p. 881). He saw Mr. McBerty spot weld a set of fan blades complete (pp. 880-881). He tested the spot-welded fans (p. 881). There were about a dozen of them (p. 881). He describes the process of testing (p. 881). Says he used one of the spot-welded fans as a test blade for some time (p. 882). The spot welds on the fans served the place of rivets (p. 882). All of the fans survived the test. In none did the blades come loose and none came back after inspection by him (p. 882). Was shown the McBerty machine and identified it as practically the same machine as the one made and used in 1901 (p. 883). He says he never personally did any spot welding on the machine (p. 883).

Captain William E. Smith

At the time of giving his testimony, Captain Smith was a captain of Engineers, United States Reserves (Rec., p. 493). His electrical education began when he was employed by the Warren Electric & Specialty Company, in January, 1900 (p. 493). He was employed as an armature winder, but did other work in the fan motor department of the company (p. 495). Brass was used for the manufacture of the fan blades for the season of 1900, but previous to the beginning of the manufacturing season of 1901 a cheap fan was built in which the blades, spiders and guards were constructed of steel (p. 494). Mr. McBerty designed this cheap fan (p. 495).

Witness saw the electric welder that was installed in the fan motor department of the factory, in 1901. This welder was set up to weld the ends of the steel guard rings (p. 495), but it was also used for spot welding steel fan blades to their steel spiders and he saw it so used (p. 495).

Three spot welds were made between each fan blade and spider (p. 496). Some of the blades and spiders were thus welded in January, 1901, soon after the machine was first set up (p. 496).

He saw at least a dozen complete fans in which the fan blades and spiders were spot welded as described (p. 496). The spot welds served the place of rivets (p. 496). He, himself, operated the welder to unite by butt welding the ends of rings or fan guards and by spot welding pieces of steel such as scrap fan blades and other pieces of steel (p. 496). He examined and operated the machine frequently during the fan season of 1901, possibly a hundred times—usually during the lunch hour, that being the time when the machine was not being used by the regular operator (p. 497).

It was the first electric welder he had ever seen (p. 497). He made tests of the strength of the welds and found that the metal would tear out before the welds would yield (p. 500). Upon being shown the welder, Defendant's Exhibit B, he identified it as the machine used by him in 1901. Produces photographs of the welder as now assembled (pp. 500-501) and produces samples of welded work made by him on such machine about a year before his examination (p. 499). He identifies the cuts in the 1901 catalogue, designated G^1 G^2 as cuts of the cheap steel-bladed fan referred to (p. 499).

He says when the welder was used in 1901, no secrecy attended its use; it was used openly and any onlooker who came to the factory could see it (p. 502). It was examined by many employees during the lunch hour and its performance as a spot welder was witnessed by them (p. 502).

Witness left the employ of the Warren Electric & Specialty Co., when its fan motor and transformer business was taken over by the Peerless Electric Company in 1902. He then went with the Peerless Company and remained there till January 1, 1905 (p. 503).

After leaving the Peerless Electric Company he went to the Ohio Works of the Carnegie Steel Company, at Youngstown, Ohio, and between February and June, 1905, while at the Carnegie Works, he built for that company an electric welder which was used for uniting pieces of half-inch rod, also for welding overlapping steel plates and for welding together overlapped pieces of resistance ribbon, face to face (pp. 503-504). He produces a blue-print of the welder so built by him for the Carnegie Company and describes the construction of the welder and its manner of use (p. 504). The welding done by the machine was spot welding. He was asked (p. 504):

"Q. 138. Where did you obtain the knowledge from which you were able to make your machine to weld in spots, as you have stated?

A. From work that I had seen done and had done myself on the machine made by F. P. McBerty at the Warren Electric & Specialty Company Factory."

On cross-examination, Mr. Smith testified that the Peerless Electric Company took over the fan motor department of the Warren Electric & Specialty Company about July 1, 1902, and that the welder went with the other effects turned over, but that he never operated the welder after this change, it being placed in a different part of the building from that in which he worked (p. 512).

He named as those who operated the welder in 1901, John Gilder, Curtis Brewer and Charles Elliss (p. 519) and named Mr. McBerty and Mr. Lipps as persons whom he remembered to have seen operating the machine (p. 520).

McElray

Mr. McElray is Assistant Chief Superintendent of the Carnegie Steel Company, of Youngstown, Ohio (Rec., p. 908). His testimony is corroborative of the testimony of Captain W. E. Smith, as to the latter's work in the building of spot welding machines at the Carnegie Company's Works in 1905, pursuant to information derived from Mr. McBerty and the latter's welder in 1901.

Mr. McElray says that he helped Mr. Smith build his welder, identifies the blue-print of the machine, Defendant's Exhibit G. Smith Welder, produced by Mr. Smith (*Ibid.*, p. 910). He further says that resistance ribbons, like samples produced, marked Defendant's Exhibit 71, Illustrating Work Done on

Smith Electric Welder were spot welded on this Smith machine in 1905 and the product resulting was put into commercial use in that year (*Ibid.*, p. 911).

Albertus C. Taylor

Mr. Taylor is at present the Vice-President and General Manager of the Taylor Welder Co., of Warren, Ohio.

Says he first saw an electric welder in May, 1903, at the factory of the Peerless Electric Company, Warren, Ohio (Rec., p. 892). It was the McBerty Welder, Defendant's Exhibit B (*Ibid.*, p. 893). Says he used the machine at the Peerless factory for making butt welds, for welding crossed wires and for welding flat sheets face to face (*Ibid.*, p. 893). He did not use pointed electrodes in the welding of the plates, face to face, but clamped the plates between the copper holding dies themselves to get the pressure on the plates, and then passed current through the dies and plates to produce the weld (*Ibid.*, p. 895). This, of course, was spot welding.

He left the Peerless Company, in 1904 (*Ibid.*, p. 895), and went with the Winfield Electric Welding Company, where from knowledge obtained of the McBerty welder at the Peerless Company, he built, in 1904 (*Ibid.*, p. 895) a spot welder for spot welding metallic white lead kegs and stove pipe elbows.

He also from knowledge of McBerty's work, built spot-welders for the market, in 1906 and 1907, but none were sold till 1908 (*Ibid.*, p. 898), there being difficulty in introducing them, because of distrust of the efficacy of spot welding in those early days.

The spot welders put out by the Winfield Company were the first spot welders ever put on the market by anyone, to the witness' knowledge (*Ibid.*, p. 899).

Mr. Taylor produced sketches illustrating the various welding machines built by him and samples of work illustrating the various applications of spot welding done on these machines.

Mr. Taylor's testimony is of importance because it shows that he, like Capt. W. E. Smith, got his knowledge of the principles of spot welding and of the practical application of those principles from the work of Mr. McBerty and from that knowledge was able to go off and build practical spot welding machines—the first to appear upon the market in this country.

Mr. Taylor, like Capt. Smith, "carried on."

Fred G. Carter

Mr. Carter is a machinist now employed at the factory of The Trumbull Steel Company, of Warren, Ohio (Rec., p. 913).

He worked for the Winfield Company in 1904-1905 at the time Mr. Taylor was employed by that company. He remembers the electric welder built by Mr. Taylor, identifies the machine illustrated in the drawing produced by Mr. Taylor (Defendant's Exhibit 69) and recalls the spot welding of strips of sheet steel and of the steel parts of pipe elbows (*Ibid.*, p. 914) by means of that machine.

He himself operated the machine to spot weld.

Other spot welding machines were built at the Winfield factory before he left there in 1907 (*Ibid.*, p. 915) and the product of these machines—stove pipe elbows—was marketed (*Ibid.*, p. 915).

William B. Ensor

Mr. Ensor is in the service department of the Peerless Electric Company, at Warren, Ohio. He testifies

that he began working for the Peerless Company in January, 1911 (Rec., p. 954); that soon after he went to work there he found among a collection of old fans and parts in the old stock house, a fan of the Warren Electric & Specialty Company's manufacture, which had a *rivetless* blade.

He was asked (*Ibid.*, p. 955):

> "Q. 9. Are you sure that the blade referred to by you was a *rivetless* blade?
>
> A. Oh, yes. No question about it. The blade was a black Japan blade and was perfectly smooth. My attention would not have been called to it if it had rivets in it.
>
> Q. 10. Where in the factory did you see the fan with the rivetless blade?
>
> A. It was on the rack of repairs and returned stuff. This returned goods was in what we now know as the stock room. There was a rack there on which returned goods were put that might be useful for repairs at some future date. These old fans are pretty valuable to us to get repair parts from.
>
> * * * * *
>
> Q. 17. What became of the fan or the rivetless blade, if you know?
>
> A. I don't know, it just disappeared."

It appears from Mr. Ensor's testimony that Newton Smith (an emissary of the plaintiff) had been at the Peerless factory looking for old fans and that witness told him about the old rivetless fan he had seen (p. 956).

It is, of course, only an inference that Newton Smith may have found the rivetless fan in question, and, in some way, have caused it to disappear. He would not be above doing a thing of that sort. It is proven that he is a spy, in the service of the plaintiff, and that, un-

der false representations, he obtained employment as shop superintendent of Mr. McBerty's company, The National Electric Welder Company, and was caught investigating the letters and records of that company, with which he had no business, and, on one occasion, surreptitiously opened the company's safe (Mrs. McBerty, Rec., pp. 976-977; F. P. McBerty, *Ibid.*, p. 889, *et seq.*).

John B. Estabrook

That the property and stock, including fan motors and fans, of the Warren Electric & Specialty Company, was purchased and taken over by The Peerless Electric Company, in the summer of 1902, is established by the records of the Peerless Company and by the testimony of Mr. John B. Estabrook, the Secretary of the company (Rec., pp. 671-672). This tends to corroborate the story of Mr. Ensor that the rivetless fan of the manufacture of the Warren Electric & Specialty Company was by him, as he testified, found in the old stock house of the Peerless Company and disappeared after Newton A. Smith had been informed of the fact.

Plaintiff's Unsuccessful Attempts to Answer the McBerty Defense

1. Although knowledge was brought home to counsel for the defendant, in the Barney-Berry case, that Mr. McBerty built and used an electric welding machine in 1901 and did spot welding on it, in that year, not only was the McBerty defense not exploited in that case, but a studied effort seems to have been made to spoil and exclude it, so that it should not be fully available to any one else in any subsequent suit brought on the Harmatta patent.

It appears that, in the fall of 1913, Mr. Clifton V. Edwards, of the firm of Edwards, Sager & Wooster, of New York City, counsel for defendant in the Barney-Berry case, sent one of his assistants, Mr. Thomas Howe, out to Warren, Ohio, to interview Mr. McBerty in regard to his early work in electric welding.

Mr. Howe saw Mr. McBerty and the latter put him in communication with a number of available persons whom Mr. McBerty thought would remember about his work and be willing to give corroborative evidence in regard to it.

Mr. Howe at that time took the affidavits of Mr. McBerty and of quite a number of other persons and secured and annexed to the affidavits specimens of spot-welding identified as having been made on the McBerty welder in the year 1901. Two of these specimens were attached to the affidavit of Mr. McBerty and another to the affidavit of Mr. Lipps, the specimen last referred to having been in Mr. Lipps' possession ever since it was made in 1901. During the cross-examination of Mr. McBerty in this case before Judge Killits these affidavits were produced and offered in evidence by the plaintiff.

Plaintiff now attempts to meet the McBerty defense by contending that, because the defense appears to be better established by the testimony offered in 1919 than it does by the affidavits procured by Mr. Howe, in 1913, the proper deduction to be made is that the additional evidence has been manufactured out of whole cloth for the purposes of this case.

We reply to this, that the testimony and the affidavits agree, in all essential particulars, as to the fact of the building of the welding machine and its use, in 1901, both for butt welding and for spot welding, as well as to its use for the spot welding of steel fan

blades to steel spiders or centers, and the present testimony merely establishes, in addition, a commercial use, on a very small scale, of the spot welded product. It is significant that the affidavits do not state that there was no commercial use.

Mr. McBerty testifies that he did tell his whole story to Mr. Howe before the affidavits were prepared, stating to him that a number of spot-welded fans were completed and went to the trade, and joining him in a search for such fans at the Peerless factory (Rec., pp. 960-961), but that Mr. Howe sought to confine the affidavits to the specimens of spot welding that had been actually preserved and were in hand.

His testimony on the last point is as follows (Rec., p. 966):

> "Q. 58. Mr. Howe, in answer to Q. 11, gives the impression that you never told him of making more than one complete fan blade; and didn't tell him any spot welded blades were assembled in complete desk fans that went out to the trade. Have you anything to say about this?
>
> A. Mr. Howe's memory, in connection with this matter, is not good; as that was gone over very thoroughly, in detail, the prior work that had been done on spot welded blades. And his final judgment was, we should confine our testimony in reference to this spot welding on actual samples we had on hand."

When Mr. McBerty gave his affidavit in 1913, he did not have the 1901 catalogue before him with which to refresh his collection, nor did he have the benefit of a conference with his principal corroborating witnesses, Major E. B. Craft and Captain William E. Smith, who have given such conclusive testimony, in

the presence of the trial court, in this case, and it is not, therefore, at all surprising that his present testimony not only corroborates, but to some extent, supplements, the statements made in the affidavits, without being in conflict therewith.

Another thing must be taken into consideration—Mr. McBerty had been advised, both by his counsel, Mr. McGill (Rec., p. 739), and by his friend, Mr. White (*Ibid.*, p. 888),.that it would be dangerous to part with evidence of his early work, as he might never see it again, and he testifies that he did, in fact, hold back and never parted with, to any one, the dated specimen, Defendant's Exhibit M. The wisdom of his having done this is shown by his failure, to this day, to recover the counterpart of Exhibit M, which was delivered into Mr. Edwards' hands, and by the latter, turned over to the plaintiff.

In weighing the statements of the affidavits, the court will give them more or less probative force, accordingly, as it conceives they were prepared by Mr. Howe with the intention of establishing or of *spoiling* the McBerty defense.

It is certain that the affidavits, as they stand, show, beyond question, the fact of the actual practice of spot welding, repeatedly, by Mr. McBerty in 1901, and, that they, taken in connection with the specimens of work actually produced and annexed to the affidavits, fully justified the setting up of the defense in the answer in the Barney-Berry suit, and the calling of witnesses, when that case was tried, to prove that defense. The fact that Mr. McBerty was put upon the stand in that suit, and was then not allowed to tell his story, simply because his priority had not been technically pleaded in the defendant's answer, looks very much like a deliberate and concerted attempt to spoil the defense,

for all time. Both counsel for the plaintiff and counsel for the defendant were aware of Mr. McBerty's claim to priority, and of the available evidence to support it before that suit was tried.

Once we get the notion that the Barney-Berry suit was not fully defended, but, by preconcert, was fought softly, to say the least, we can well understand how the affidavits taken by Mr. Howe may have been artfully framed to satisfy Mr. McBerty and yet lend color to the argument of abandoned experiment by a studied failure to include anything looking like the commercial use of spot welding by Mr. McBerty.

2. When Mr. McBerty testified before the court in this case that the 1901 and the 1902 catalogues contained illustrations of the "ironclad" G-2 fan, and told the court that such illustrations were made from a photograph of one of the actual spot welded fans, and pointed out that, whereas, in all the other illustrations of fans to be found in those catalogues, the rivets employed to connect the fan blades to their spiders were shown, and further identified the cut in the "American Electrician" of March, 1901, as illustrating also the spot welded G-2 fan,—plaintiff felt the force of the blow and set about to try to discredit the illustrations.

To that end, plaintiff called a photographer, Mr. Wilbur F. Turner (Rec., p. 306), who testified that it would be easy to photograph a fan whose blades had been riveted, and then prepare the negative so that the rivets would not show in a positive printed from the negative, and that, in his judgment, was precisely what had been done to the negative taken of the G-2 fan, the photographer having failed to put back the rivets in the negative, as had been done, it was claimed, in the case of the other photographic illustrations shown in the catalogues!

Of course, nobody ever doubted that a photographic negative could be so manipulated as to not truly represent the object photographed; but it is certainly a strain upon one's credulity to believe that this particular kind of alteration was made, back in 1901, on the negative of this particular critical, G-2 fan, whose identity, as a rivetless fan is so well established by evidence outside the photograph.

We think the court will accept the straightforward testimony of Mr. McBerty and his witnesses to the fact that the fan was a rivetless fan and that the illustration correctly portrays it, rather than the expert testimony of this willing photographer, procured to testify eighteen years after the event to meet a serious exigency.

3. Another attack made upon Mr. McBerty's evidence was made through the deposition of Mr. Richard L. Binder, of Philadelphia, and through Mr. James H. Gravell plaintiff's stop-gap, in the latter's fifth and sixth depositions.

Mr. Gravell, in his fifth deposition (Rec., p. 361) took great satisfaction in pointing out that the specimen of fan blade and spider, Defendant's Exhibit M, introduced by Mr. McBerty as a specimen of spot welding done by him in 1901, showed two (2) rivet holes and that illustrations of fans having two (2) rivets were not to be found in any of the catalogues or trade illustrations of Peerless fans until the year 1909, and that in the issue of the "Electrical World" of March 4, 1909, the blades of the Peerless fans were first shown as having been attached by two (2) rivets each. The deduction, of course, sought to be drawn from all this was that Defendant's Exhibit M, and all other specimens produced by Mr. McBerty that

showed a two-rivet connection, were faked and were really made from parts first used in the manufacture of the Peerless fans in 1909.

In an attempt to make this point stronger, Mr. Gravell, in his sixth deposition (Rec., p. 382) testified that he had found at the J. B. Shannon Hardware Company's store, in Philadelphia, an old fan (Plaintiff's Exhibit 51, Fan Purchased by Gravell), corresponding as to base, standard and other parts to the G fans illustrated in the 1901-1902 catalogues, and Mr. Binder, in his testimony, attempted to identify this fan as a sample of the cheap fan like those put out by the Warren Electric & Specialty Company, somewhere around 1901-1902 (Rec., p. 385), which had the blades and spider arms attached by three rivets, instead of by two rivets, the spider being a cast brass spider and the blades being of steel (*Ibid.*, p. 383). This was supposed to be further proof that the Warren Electric & Specialty Company had never made any two rivet fan blade connections, especially two-rivet connections for uniting steel blades to steel spiders, as early as 1901.

But this latest attempt to discredit the testimony of Mr. McBerty and his corroborating witnesses was completely annihilated by defendant's proving, on rebuttal, from the records of the Peerless Electric Company, the successor of the Warren Electric & Specialty Company, that, for the season of 1901, the Warren Electric & Specialty Company issued and sent out to the trade four separate printed illustrated bulletins, namely,—

(a) Bulletin No. 1, illustrating fan A-2 having cast brass center and three (3) rivets per blade;

(b) Bulletin No. 2, illustrating fan A-6, showing stamped steel center and two (2) rivets per blade;

(c) Bulletin No. 3, illustrating fan E-2 having cast brass center and three (3) rivets per blade; and

(d) Bulletin No. 4, illustrating fan G-2 with stamped steel center and blades spot welded thereto, the illustration of this last bulletin being like the illustration of the G-2 fan in the catalogue of 1901 and 1902, and showing a rivetless fan.

Mr. McBerty testified to the character of the fan blades and spiders shown in these several exhibits (Rec., p. 1010), and Mr. George B. Sawyer, of the Peerless Electric Company, testified (*Ibid.*, p. 1007) that the scrap book containing the exhibit bulletins referred to by Mr. McBerty was produced from the archives of the Peerless Company and was a book with which he was familiar while he was employed by the Warren Electric & Specialty Company during the years 1901-2.

Mr. McBerty further testified that the spider and fan blades on Plaintiff's Exhibit No. 51 were not on the fan as originally put out, but represent some vagrant spider and blades that had been attached to the shaft of the fan at some later period, and that the rivets shown on the blades of the exhibit are machine headed, whereas the Warren Electric & Specialty Co. had no riveting machine in 1901-2 (Rec., p. 1013). He further testifies that the shafts of various desk fans are of the same diameter and are so built to accommodate any fan spider. It appears, therefore, that these attacks of the plaintiff upon the integrity of the testimony of Mr. McBerty and his witnesses in regard to the G-2 fans have reacted upon the plaintiff and have had the effect of materially strengthening the defendant's case.

On the whole, the evidence is satisfactory and con-

clusive (1) that there was practiced the method and (2) that there was made the product of the Harmatta patent, by Mr. McBerty, in the year 1901.

The practice of the method could, of course, only be proved by the testimony of those who practiced it or saw it practiced. Such proof has been adduced. The machine by which the method was practiced has been preserved and is in Court and has been fully identified by many witnesses. The spot-welded products or articles resulting from the practice of the method, by means of the machine, are in Court—several samples of them—and their identity has been fully established by witnesses of the highest standing. The defendant could do no more. It has satisfied the requirements in such cases.

The number of times the method was practiced and the number of times the product was produced is quite immaterial. A single, well authenticated instance of the practice of an invention has many times been decided, by highest authority, to be sufficient to defeat a patent.

In Egbert vs. Lippman, 104 U. S., 333, it appears that Barnes, the patentee, made a set of corset steels and presented them to his fiance, who wore them for more than two years prior to the application for his patent. Proof of this fact, invoked the following language from the Court:

> "We observe, in the first place, that to constitute the public use of an invention it is not necessary that more than one of the patented articles should be publicly used. The use of a great number may tend to strengthen the proof, but *one* well defined case of such use is just as effectual to annul the patent as many" (citing cases).

Coffin vs. Ogden, 18 Wallace, 120, is to the same effect. In that case, in a suit for infringement of a lock patent, defendants pleaded the manufacture and use, by one Erbe, of a lock embodying all the attributes of complainants. It was proven that Erbe made but three of such locks, one of which was in evidence; but the proof was convincing as to the fact of his having made *a lock* of the type under discussion. The Court said (p. 124):

> "The invention or discovery relied upon as a defense must have been complete, and capable of producing the result sought to be accomplished; and this must be shown by the defendant. The burden of proof rests upon him, and every reasonable doubt resolved against him. If the thing were embryonic or inchoate; if it rests in speculation or experiment; if the process pursued for its development has failed to reach the point of consummation; it cannot avail to defeat a patent founded upon a discovery or invention which was completed, while in the other case there was only progress, however near the progress may have approximated to the end in view. The law requires not conjecture, but certainty. If the question relate to a machine, the conception must have been clothed in substantial forms which demonstrate at once its practical efficacy and utility. The prior knowledge and use of a *single person* is sufficient.
>
> The number is immaterial."

In Brush vs. Condit, 132 U. S., 39, the Brush patent for improvement in electric lamps was sued upon and the use of a single lamp made by one Hayes for more than two years prior to the application, was set up as a bar. It appears that Hayes made but one lamp, which was used in and about the mill of Wallace &

Sons, in the ordinary way. Justice Blatchford, in expressing the opinion of the Court that this was a sufficient public use, said:

> "The case is that of the public, well known, practical use, in ordinary work, with as much success as was reasonable to expect at that stage in the development of the mechanism belonging to electric arc lighting, of the exact invention which was subsequently made by the patentee, and, although only one clamp and one lamp were ever made, which were used together two and one-half months only, and the invention was then taken from the lamp and was not afterwards used with carbon pencils, it was an anticipation of the patented device under the established rules upon the subject * * *."

The Court of Appeals for the Seventh Circuit held, in U. S. Mineral Wool Co. vs. Manville Covering Co., 125 Fed., 770, that the practice of a process for producing wool, on two separate occasions, and no more, invalidated a patent for such process, though it appeared that no efforts were made to further use the process.

Judge Baker, speaking for the Court, said:

> "If the patent is not void for indefiniteness (citing cases), we think the process was anticipated by the prior use at Joliet. What Pettigrew and Gleason did was not an abandoned experiment. They knew the product they wanted to get. They experimented with hardened slag alone unsuccessfully * * *. The process they discovered in 1884 did not lapse into a lost art. In 1886 they used it in successful manufacture. Why the Illinois Steel Co. did not have them continue is not clear, but they were not the masters. Nevertheless, whenever they have been called upon since 1884 to explain the process they have done

so. The use was not secret. The process was practiced by Pettigrew and Gleason and those who assisted and was open to the observation of the employes generally and of all who passed through the plant. We think there was abundant publicity. Coffin vs. Ogden, 18 Wall., 120; Brush vs. Condit, 132 U. S., 39."

This case was tried in open court and the McBerty defense exploited in the presence of the Judge.

In its opinion the trial court said:
(Rec., pp. 40-41).

"We have seen the witnesses as they spoke on the stand. The naturalness of their stories suggests want of co-operation. They corroborate each other in the varying scopes of their experiences with Exhibit B. Their testimonies are to such important things that, if unreliable in substance, there is no escape but to assign willful perjury as the cause by a number of men whose credibility is not subject to attack from anything that appeared before us.

The testimony of Smith, Craft, Powers, Gilder, McDonald, Taylor and Ensor and Brown (by affidavit) is all perjured—every one of these men, as well as Lipps and McBerty, is foresworn—if this allegation of prior use is substantially untrue. Perjury is unthinkable with such men as these men appear to be. Besides, their stories have in them no element of the unusual or unexpected. What they say McBerty did in 1901 is just what we can see one interested in the matter might readily do in due course of satisfying his interest. The incident was a logical step, plainly indicated in the condition of the prior art."

The conclusiveness of the findings of fact of the trial judge is upheld by the great weight of authority.

We give below citations from opinions of this Court and of the various Circuit Courts of Appeals on the subject:

Supreme Court Cases

"A special finding by the court upon issues of fact, where the parties or their attorneys have duly filed a stipulation, waiving a jury, has the same effect as a verdict, and is not subject to review by this court except as to the sufficiency of the facts found to support the judgment."
Tyng v. Grinnell, 92 U. S., 467.

"Where a case is tried by the Circuit Court without a jury, and it makes a special finding of facts, with conclusions of law, alleged errors of fact are not, on a writ of error, subject to revision by this court, if there was any evidence on which such findings could be made."
Hathaway v. First Nat. Bank, 134 U. S., 494.

"Where a case is tried by the court, a jury having been waived, its findings upon questions of fact are conclusive in the courts of review."
Dooley v. Pease, 180 U. S., 126.

"Under R. S. Secs. 649, 700 and 1011, findings of fact have the same effect as the verdict of a jury, and this court does not revise them but merely determines whether they support the judgment."
U. S. v. Fidelity Co., 236 U. S., 512.

"The rule which gives conclusive effect to a finding made by a judge who saw the witnesses, when there is testimony consistent with it and the finding depends on conflicting testimony or the credibility of witnesses, is peculiarly applicable in a case wherein a patent is assailed by oral evidence of an alleged unpatented anticipation."
Adamson v. Gilliland, 242 U. S., 350.
See also *Wiscart v. D'Anchy*, 3 How., 320.

Circuit Court of Appeals Cases:

FIRST CIRCUIT.

"He (the trial judge) had so much better opportunity than this court to judge correctly the accuracy and credibility of the various witnesses that, on familiar and established principles, his conclusions will not be disturbed unless they are clearly wrong."

Fuller v. Reed, 249 Fed., 158.

SECOND CIRCUIT.

"The testimony is not direct, but is circumstantial, and somewhat conflicting * * *. But on examination of the record it appears that there is credible testimony which supports the findings of the court below * * * and we think that finding is under all circumstances conclusive upon this court on this appeal."

Pierce v. Dock Co., 265 Fed., 148, 153.

"We must, therefore, accord to the findings of fact, in a case tried to the court without a jury, there being a stipulation in writing waiving the jury, the same effect as we would give a verdict."

Nashville Co. v. Barnum, 212 Fed., 634, 639.

"We should not reverse his finding upon a mere pure question of fact, where the evidence justifies the finding, even if we might have reached a different conclusion upon the evidence."

Brookheim v. Greenbaum, 225 Fed., 763, 764.

THIRD CIRCUIT.

"By stipulation a jury was waived and the case tried by the judge. He found a verdict for the plaintiff * * *. Where, as here, a case is tried by a judge, the findings of fact by a court are conclusive, unless there is no evidence to sup-

port them. Hathaway v. First Nat. Bank, 134 U. S., 494."

Washington Co. v. Murray, 211 Fed., 440, 447.

"By stipulation, under R. S. 649, the parties waived trial by jury. The findings of the judge, under the statutory submission, having the effect of a verdict (Lehnan v. Dickson, 148 U. S., 71), the first question arises: Was there competent evidence on which to base the finding that Peet's account was overdrawn?"

Elliott v. Peet, 202 Fed., 434, 436.

FOURTH CIRCUIT.

"Every finding of fact made by the District Court, having reasonable support in the evidence and tending to support the judgment, is binding on this court."

Virginia Co. v. Charles, 254 Fed., 379, 382.

"It is familiar doctrine that the findings of the trial court in an equity case are presumptively correct, and will not be set aside by an appellate tribunal, unless they are based upon an obvious error of law or a serious mistake in dealing with the facts."

McKeithan Co. v. Fidelity Co., 233 Fed., 773, 774.

FIFTH CIRCUIT.

"Where jury was waived and all matters submitted to the judge, his findings on issues of facts are, at least, entitled to as much consideration as a verdict and so will not be disturbed on appeal, if there was evidence furnishing a basis therefor."

Bain v. White, 256 Fed., 428.

"It is settled that an appellate court of the United States does not weigh the evidence."
Barber Co. v. Brown Mach. Co., 258 Fed., 1, 3.

"Counsel seem to overlook the rule that a federal appellate court does not weigh the evidence, though, of course, the court must be satisfied, as we are here, that there is proper evidence which in law is sufficient to support the verdict."
Lake Erie Co. v. Schneider, 257 Fed., 675, 679.

"The entire testimony in the case, except Rich, who did not attend the conference, was taken in open court. There was express testimony supporting the court's conclusion; and this conclusion we are bound to accept, unless the evidence preponderates against it."
Escanaba Co. v. Burns, 257 Fed., 898, 901.

"We are disposed to treat this as a special finding, though, whether general or special, it has the effect of the verdict of a jury. Hence the only inquiries open to this court are * * * whether the evidence tends to support the ultimate findings * * *. This results from the statutes and the decisions, Secs. 649, 700 and 1011, R. S. U. S.; Morris v. Jackson, 76 U. S., 125; Runkle v. Burnham, 153 Fed., 216; U. S. v. U. S. Fidelity Co., 236 U. S., 512; Chicago Co. v. Barrett, 190 Fed., 118 (CCA 6); Mason v. Smith, 191 Fed., 502 (CCA 6)."
Turner v. Schaeffer, 249 Fed., 654, 656.

"Not only must we apply the familiar rule that we will not overturn the fact findings of the trial judge, save in a very clear case * * *."
King v. Weiss Co., 266 Fed., 257, 259.

"Where the trial court has seen and heard the witnesses, we are always reluctant to set aside its finding of fact."

City of Toledo v. Toledo Co., 259 Fed., 450, 453.

"In accordance with our settled practice we must give great weight to the conclusions of the trial judge. If Mr. and Mrs. Snodgrass told the truth in their testimony, the petitioner has no case. Their veracity was the controlling question, and this may be so far judged by their manner and by the atmosphere, which cannot be reproduced in the printed record, that only when 'there is a decided preponderance against the judgment' will an appellate court reverse such a decree. Cleveland v. Chisholm, 90 Fed., 431, 434 (CCA 6); Monongahela v. Schinnerer, 196 Fed., 375 (CCA 6)."

Pugh v. Snodgrass, 209 Fed., 325, 326.

"The trial judge had the advantage of seeing and hearing all the witnesses except the bankrupt; and every experienced lawyer knows what that means. While equal advantage exists here as respects the deposition of the bankrupt, yet this is not so as to the testimony of appellant; the important element of demeanor of the witness, like that of every other witness who testified before the Court is, of course lacking.

Indeed, the rule in such circumstances is not to disturb the judgment of a district court unless it is overborne by the clear weight of the evidence as disclosed by the record (citing cases)."

Carey v. Donohue, 209 Fed., 328, 333.

"Where an action at law is by stipulation tried to the Court without a jury under R. S. U. S., 649 and 700, the findings of fact made by the court are not reviewable by an appellate court, if there is any competent evidence on which they could have been made."

Chautauqua Inst. v. Zimmerman, 233 Fed., 371.

"Findings of fact by the trial judge in an equity case will not be disturbed on appeal, unless the evidence preponderates against them."

Estep v. Kentland Co., 239 Fed., 617.

SEVENTH CIRCUIT.

"As the trial judge saw and heard the witnesses, his findings upon the issues of fact will not be set aside, unless the cold type of the record demonstrates that a material finding was either unsupported by evidence or was made in the face of a clearly ascertainable preponderance to the contrary."

Aetna Co. v. Davidson Co., 257 Fed., 68.

"The court heard the evidence of the witnesses, and had before it the alleged infringing devices * * *. The evidence of the witnesses is contradictory, and in so far as the decree is predicated thereon, we cannot disturb it."

Blettner v. Gill, 251 Fed., 81, 82.

"It is true the weight of this testimony is somewhat shaken by other evidence. * * * But the weight of his testimony was for the District Judge to determine."

Deister Co. v. Deister Mach. Co., 263 Fed., 706, 709.

"The rule is that a finding of the trial court on an issue of fact will not be disturbed on review, unless the finding is clearly against the weight of the evidence."

Winter v. Bostwick, 212 Fed., 884, 887.

"The facts found by the chancellor will be presumed correct, unless the record shows an egregious blunder in the consideration of the evidence, or an error in the application of the law, resulting in manifest injustice" (citing cases).

"The pertinent issue of fact was determined solely upon the testimony of James R. McKay, and counsel urges that the foregoing rule applies only where there is a conflict in the evidence. This is not so. The evidentiary facts may all be made known from the month of a single witness, and yet the ultimate fact as determined by the chancellor is just as persuasive as if the evidentiary facts had come from many witnesses."

Weld v. McKay, 218 Fed., 807, 809.

EIGHTH CIRCUIT.

"Unless we are to completely disregard the rule that the finding and decree of a chancellor, who has heard the witnesses, will not be disturbed, except in a clear case, the decree ought to be affirmed."

Hamlin v. Grogan, 257 Fed., 59, 60.

"It was said in Adamson v. Gilliland, 242 U. S., 350, that a patent case is preeminently one for the application of the practical rule that so far as the finding of the master or judge who saw the witnesses depends upon conflicting testimony, or upon the credibility of witnesses, or so far as there is any testimony consistent with the finding, it must be treated as unassailable."

Fed. Co. v. Pick & Co., 251 Fed., 894.

"On this appeal the controversy is purely one of fact. The questions raised are: First, was the court below wrong in holding that the deed from Barnes to Bates was genuine * * *?

To secure a reversal upon such a basis as that just mentioned the appellant must convince us not only that the trial court may have been wrong, but that it was manifestly wrong. There must, under the holdings of this court, have been an 'obvious error' of law or a 'serious mistake' in dealing with the facts. (Cases cited.) The error

must be 'clear and palpable.' Babcock v. De Mott, 160 Fed., 882. The conclusion of the trial court is presumptively right. Some distinction relieving from this rule is claimed in the present case because the testimony was not taken before the judge but before an examiner, and it is said that under such circumstances this court is in as favorable a situation to deal with the matter as was the court below. U. S. v. Booth Co., 203 Fed., 423 (this circuit) is cited to this point. But the question is not so much one of situation to decide as of where the law places the primary determination of questions of fact. While no doubt the circumstances that the district judge personally heard the witnesses tends to strengthen the presumption in favor of his conclusions—a consideration mentioned by this court in Coder v. McPherson, 152 Fed., 951 and Harper v. Taylor, *supra,* by the Circuit Court of Appeals for the Sixth Circuit in Mt. Vernon Co. v. Wolf Co., 188 Fed., 164,—the fact that he did not hear such witnesses, but that the proofs before him were entirely by deposition or upon examiner's report, does not destroy the presumption. Such still exists in favor of his conclusion. To hold otherwise would be to make this the court of first instance. The District Court is not in such matters a mere conduit. Our functions are simply to guard against manifest error on its part, and this is true whether such arises upon hearing witnesses or upon reading a record."

U. S. v. Marshall, 210 Fed., 595, 597.

"When an action at law is tried without a jury by a federal court, and it makes a general finding, or a special finding of facts, the act of Congress forbids a reversal by the appellate court of that finding, or the judgment thereon, 'for any error of fact' (R. S. U. S., Sec. 1011), and a finding of fact contrary to the weight of the evidence is an error of fact."

Wear v. Imperial Co., 224 Fed., 60, 63.

"The rule is firmly established by the Supreme Court and has been repeatedly applied by this Court: That where the chancellor has considered conflicting testimony, made his findings and decree thereon, they will be held by the appellate courts to be presumptively correct, and unless an obvious error has intervened in the application of the law, or some serious mistake has been made in the consideration of the evidence, the findings must stand." (Cases cited.)

Nichols v. Elken, 225 Fed., 689, 692.

NINTH CIRCUIT.

"The trial court held there was no infringement of the patent in suit.

In such a case, the trial court having the advantage of seeing and especially examining the material which it is claimed infringes, an appellate court, without such advantages, will not disturb the conclusions reached, unless it appears clearly that the finding is against the obvious weight of the testimony."

Diamond Co. v. Webster Bros., 249 Fed., 155 158.

"That conclusion was sustained by direct testimony which the court below credited, and we regard it as binding on this court."

Hathaway v. Ford Motor Co., 264 Fed., 952, 954.

"Allegations of fact made in defense of the action * * * were negatived by the findings of the trial court, and under the well established rule such findings are conclusive upon us, however convincing we might otherwise consider the argument of plaintiff in error that upon the evidence such findings should have been otherwise. Tyng v. Grinnell, 92 U. S., 467; Dooley v. Pease, 180 U. S., 126."

Nat. Surety Co. v. Globe Co., 256 Fed., 601, 602.

"The findings of fact are all based upon evidence which is conflicting, and which was taken in open court, and they will not be disturbed by this court, in the absence of a showing that in arriving at the same, the court below erroneously applied some rule of evidence or found contrary to the decided weight of the testimony."

Leggat v. M'Lure, 234 Fed., 620, 621.

CONCLUSIONS

It is respectfully submitted that a careful examination of the record in this case will justify the Court in reaching the following conclusions, among others:

1. That Johann Harmatta contributed nothing new to the art of electric resistance-welding, but that everything that he disclosed by way of method or of product, was known to and disclosed by others prior to the date of his alleged invention.

2. That the Harmatta patent, as to all of its claims, is anticipated by the work of Adolph Rietzel, conducted in the factory of plaintiff's predecessor, long prior to the date of Harmatta's alleged invention.

3. That the plaintiff is estopped to deny Rietzel's priority over Harmatta.

4. That the Harmatta patent, as to all of its claims, is anticipated by the prior work of F. P. McBerty, at Warren, Ohio, in the year 1901.

5. That the Harmatta patent is invalidated by the proven prior invention of Sebastian Ziani de Ferranti, in May, 1903.

6. That the Harmatta patent is invalid as to all of its claims, because Harmatta never made the statutory oath to any of such claims.

7. That the Harmatta patent is invalid because the delay in its grant was first employed to enable the

plaintiff to retain the dominance of the Rietzel patent, for the same invention, and, then, to secure a belated second patent, which had the effect of prolonging plaintiff's protection to twenty years, instead of limiting it to the statutory period of seventeen years.

8. That the adjudication in the Barney-Berry suit is so discredited as to entitle it to little or no weight, favorable to the plaintiff, in the determination of this cause.

9. That the conduct of the plaintiff and its predecessor has generally been so devious and inequitable as to disentitle it to the favorable consideration of a court of equity.

10. That the decree of the court below was right and should be affirmed.

MELVILLE CHURCH,
Counsel for Defendant-Respondent.

November 3, 1923.

Mr. Frederick P. Fish, with whom *Mr. J. L. Stackpole* and *Mr. H. F. Lyman* were on the brief, for petitioner.

Mr. Melville Church for respondent.

MR. JUSTICE SANFORD delivered the opinion of the Court.

This is a suit in equity brought by the Thomson Spot Welder Company in a Federal District Court in Michigan for the infringement of United States patent No. 1,046,066 for improvements in electric welding, issued December 3, 1912, to the plaintiff's predecessor in title, as assignee, upon an application filed by Johann Harmatta, December 3, 1903. The chief defenses were anticipation, lack of invention, prior public use, and estoppel. The District Court sustained all of these defenses, and dismissed the bill. 268 Fed. 836. The Circuit Court of Appeals—one judge dissenting—held the patent invalid for lack of invention, and, without considering the other defenses, affirmed the decree of the District Court. 281 Fed. 680. On account of a conflict with a prior decision of the Circuit Court of Appeals for the First Circuit, in *Thomson Electric Welding Co.* v. *Barney & Berry,* 227 Fed. 428, in which the patent had been held to be valid, this writ of certiorari was granted. 260 U. S. 718.

In the present case both the District Court and the Circuit Court of Appeals have held that Harmatta's improvement involved merely the exercise of mechanical skill and not invention. The question whether an improvement requires mere mechanical skill or the exercise of the faculty of invention, is one of fact; and in an action at law for infringement is to be left to the determination of the jury. *Keyes* v. *Grant,* 118 U. S. 25, 36, 37; *Holmes* v. *Truman* (C. C. A.), 67 Fed. 542, 543; *Hall* v. *Wiles* (C. C.), 2 Blatchf. 194, 11 Fed. Cas. 280, 283; *Poppen-*

husen v. *Falke* (C. C.), 5 Blatchf. 46, 19 Fed. Cas. 1052, 1054; *Shuter* v. *Davis* (C. C.), 16 Fed. 564, 566; *Blessing* v. *Copper Works* (C. C.), 34 Fed. 753, 754. Ordinarily, therefore, the case would call for the application of the well settled rule that the concurrent findings of the lower courts on questions of fact will be accepted by this Court unless clear error is shown. *Wright-Blodgett Co.* v. *United States*, 236 U. S. 397, 402; *United States* v. *State Investment Co.*, 264 U. S. 206, and cases there cited. We think, however, that this rule should not be strictly applied in cases brought here because of a conflict of decision in the different circuit courts of appeal, and have therefore given consideration to the question as to which of the decisions upon this question of fact, in the light of the prior art, is based upon the sounder reasoning. At the outset it is to be noted that in the First Circuit there was not a concurrent finding on the question of patentability; the District Court having found, as did the two courts in the present case, that the patent was invalid for want of invention. 227 Fed. 428, 433.[1]

Welding is the art, practised immemorially, of uniting two pieces of metal in one piece by heating those portions which are to be welded to a temperature at which they become plastic and then pressing them strongly together so as to effect a union; as exemplified by a blacksmith when heating in a forge the two pieces to be welded and hammering them together.

The art of electric welding, which was invented in 1886, was well advanced when Harmatta filed his application, having been disclosed in various prior patents for uniting the abutting ends of metal bars, wires, etc., uniting the over-lapped edges of metal sheets, plates, etc., and other purposes.

[1] The opinion of the District Court is published with that of the Circuit Court of Appeals.

The patent in suit relates to that branch of electric welding known as spot welding, by which two sheets or plates are welded together face to face, in spots, as a substitute for riveting; this being accomplished by placing the two sheets between two pointed electrodes applied to their exterior surfaces, opposite to one another, which heat the sheets to the welding temperature and exert the required pressure in the line between the points of the electrodes, resulting in welding together the inside faces of the sheets in the spot on that line.

The reasons for which the petitioner claims that this improvement is patentable are thus summarized in its brief: "Harmatta produced a new result, namely a small round weld (a spot weld) uniting two plane sheets of metal at any place in their meeting faces. This was radically new . . . 2. To make this spot weld Harmatta manipulated the articles with which he dealt, namely the sheets, in a new way by indiscriminately superimposing one upon the other and he made his electrodes perform a function, which no electrodes, used in electric welding, had ever before performed. 3. In so doing he carried out a new technical process, that is, the electric current, which generates the welding heat, behaved and operated in an entirely new way, . . . and he applied the welding pressure to a condition, which seemed to make such application impossible."

The opinions of the two District Courts and of the Circuit Court of Appeals for the Sixth Circuit holding that the patent in suit was lacking in invention, are based, in each instance, on a detailed and analytical consideration of the prior art. We take the following extracts from the well considered opinion of the Circuit Court of Appeals:

"The art of electric resistance welding was old and far advanced in 1903, when the Harmatta patent was applied for. Prof. Elihu Thomson . . . was a pioneer in

that art. In 1886 he obtained process and apparatus patents . . . for so-called butt welding, which involved the uniting of the abutting ends of metal wires, bars, etc., by applying heat at the joint and the adjacent surfaces by means of electrodes, and pressing the two pieces together when heated to welding temperature. There was here true resistance welding, with pressure of the parts involved, although the electrode did not exert the welding pressure. In 1889 Thomson obtained a patent . . . for electric riveting, which involved the heating of the rivet when in place by means of a current passed through it by the use of electrodes, under pressure thereon, the effect being not only to swage the rivet and weld it to the adjoining metal, but apparently (when desired) to weld together, in part at least, the portions of the plates immediately adjoining the rivet. In 1891 Thomson obtained a patent . . . for what is called lap-welding. While the specification states that the invention is specially adapted to the welding of the overlapped edges of plates, it . . . expressly includes 'welding together strips, sheets, plates, or bars of metal where it is desirable to form a joint of considerable length.' According to the specification, 'the surfaces to be welded are pressed together to form a union,' the work being fed in the longitudinal direction of the joint 'through suitable pressure devices (preferably roller electrodes), the work being properly arranged, so that the pressure devices will press the surfaces to be welded together and simultaneously passing the electric current through the work *at the point of pressure.*' The electrodes were employed to exert the welding pressure. The specification further states that 'as the work is passed through such rolls with a continuous motion *each point,* as it comes between the rolls, is heated and the surfaces pressed together.' . . . In 1893 Thomson obtained a patent . . . relating particularly to soldering sheet metal pieces flatwise, either

by the use of solder or (when applied to tin plates) by melting the tin sufficiently to establish union thereby. The electrodes, in the form of clamps or otherwise, served not only to supply the necessary heat, but to exert sufficient pressure upon the overlapped sheets to effect their union. A roller electrode is disclosed, performing the double function of heating and pressing, and having its periphery corrugated or grooved . . . This was, to say the least, electric resistance spot soldering. In 1897 Robinson received a patent . . . on so-called projection welding, as specially applied to the welding of a splice bar to the web of a railroad rail, the splice bar having upon its inner face a number of projections which by the application of the heating current are fused, and by pressure made to form welds between the projections on the bar and the fused opposing portions of the rail. Kleinschmidt, in 1898, took out a patent . . . for a similar process, and by methods not essentially unlike those of Robinson.

"Whether or not the Thomson so-called lap-welding invention should be regarded as an absolute anticipation of the Harmatta patent, we think the state of the art to which we have referred left no room for invention in Harmatta. . . . We see no distinction upon principle between plane-face welding and lap-welding; the former certainly embraces the latter. If Thomson's roller electrode device was capable of welding a line or seam in a metal lap joint, it was readily adaptable to line-welding together coterminous plane-face plates. . . . We think Thomson's lap-welding invention was in essence a welding in points. In fact, his line seam was merely a succession of adjoining points. . . . It satisfactorily appears that, although Thomson's roller electrodes in the form shown in the patent were not practicably adapted to commercial spot-welding as disclosed by the Harmatta patent, they could readily be made to do such spot-

welding by the use of suitable projections upon the face of the rolls (Thomson later did spot-soldering by the use of such projections); and assuming that pin electrodes were essential to successful commercial spot-welding, that form of electrodes was old, as illustrated by Thomson's electric soldering patent. . . . In our opinion the art of soldering is analogous to that of welding. . . . By the use of enough more heat Thomson's soldering device could readily have effected spot-welding. . . . No essential difference in principle between heating at points and heating in spots is apparent. Projection welding partakes, though not in so pronounced a sense, of the nature of spot-welding. . . . We agree with Judge Dodge [227 Fed. 428] that Harmatta's idea of 'making his electric welds small in area rather than large in comparison with the areas of the opposed surface to be joined and isolating them, so as to leave each surrounded by a comparatively large area of unwelded surface,' does not involve invention in view of the prior art. In other words, given the desire for a welding in spots, naturally enough suggested by the prior art and by its commercial development, we think Harmatta's specific application of the principles of that prior art involved only the skill of the expert mechanic. Not only every principle, but every electric and mechanical process, involved in the Harmatta claims, was well known in the prior or directly analogous arts, or in mechanical arts generally. We cannot think, in view of the prior art, that invention is to be found in the considerations, separately or collectively, that in Harmatta no bodily movement of the sheets is required, that the current is localized and pressure exerted solely by the electrodes, or by the difference in the form of the electrodes, or by the difference in amount of extruded metal, as compared with some of the earlier applications of resistance welding. Although invention is not necessarily negatived by the fact that each element of the

combination is old, the question of fact whether the combination itself involves invention in view of the prior art is always present.

"Our conclusion of noninvention, based upon a review of the prior art, is materially strengthened by the serious doubt whether Harmatta thought, when he filed his patent application, that he had patentably invented anything by the disclosure of spot-welding, as a process or product distinct from point-welding or line-welding, as well as by the fact that others previous to the grant to Harmatta, and apparently in ignorance of Harmatta's claimed invention, successfully practiced the art of spot-welding. . . .

"The patent issued nine years after the application was filed, and after numerous vicissitudes and amendments (including the entire elimination of the roller-electrode feature), and after the application had been placed in interference with the claims of Adolph Rietzel, to whom a patent had previously been issued on July 20, 1909. . . . From the beginning Rietzel's application was owned by plaintiff's predecessor. The interference was declared in favor of Harmatta, for Rietzel's failure, as the junior party to the interference, to take testimony in support of his claim of priority; plaintiff's predecessor at the time owning both the Harmatta application and the Rietzel patent.[2] . . . But the fact that the award of priority was not based upon an adjudication on the merits tends to weaken its force. It, however, convincingly appears . . . that in 1898 (and about five years before Harmatta's application) Rietzel, while in the employ of plaintiff's predecessor, in several instances successfully joined two pieces of lapped metal at isolated spots by means of a Thomson butt-welding machine; the

[2] The proceedings in the Patent Office are set forth at length in the opinion of the District Court (pp. 855 *et seq.*).

sheets of metal being united by pressing them together and at the same time passing the heating current from one electrode (or so-called contact) to the opposite electrode, at the selected spot on the meeting surface of the plates, the spots being restricted in area, so as to leave well-defined and comparatively extensive areas of no-union completely surrounding the spots—one of the electrodes or contacts used being of standard size and form, the other being reduced by cutting down to a diameter of about three-eighths of an inch. . . . Rietzel's experience strongly discredits inventive quality in what Harmatta did several years later, including his disclosure of the use of pin-electrodes. The fact also appears . . . that at various times, ranging from two years to five or six years, before the issue of the Harmatta patent, and apparently in ignorance of his asserted invention, various manufacturers put out or used spot-welding machines with commercial success. . . . These experiences also tend to discredit invention in Harmatta. It follows, in our opinion, from what has been said, that the effect of the great commercial success of the Harmatta invention in the hands of plaintiff is entitled to little weight upon the question of the invention, even were that question otherwise in doubt, which we think it is not." (pp. 682 *et seq.*).

The opinion of the Circuit Court of Appeals for the First Circuit, on the other hand, contains only general allusions to the prior art and no analysis of the prior patents. While, in considering the defense of anticipation, it is said that the soldering art was remote, the only statement in the opinion bearing directly upon the defense of want of invention, is that "in view of the further proposition that the presumptions in favor of the patent are so far supported in this case by the insistency of the defense, and the comparatively enormous expense involved in maintaining it, we cannot question the present

validity of the patent with reference to all propositions involved in the word 'patentability'". (p. 436.)

The conclusion of fact reached by the Circuit Court of Appeals for the Sixth Circuit, as set forth in its opinion, that in the light of the prior art Harmatta's improvement was lacking in invention, commends itself to our judgment. It involves no error in law. Therefore, without considering the other defenses presented, the decree of that court is

Affirmed.

THOMSON SPOT WELDER COMPANY *v.* FORD MOTOR COMPANY.

CERTIORARI TO THE CIRCUIT COURT OF APPEALS FOR THE SIXTH CIRCUIT.

No. 120. Argued December 5, 1923.—Decided June 2, 1924.

1. The question whether an improvement in the arts involved invention or only mechanical skill, is a question of fact. P. 446.
2. The rule in this Court to follow concurrent findings of fact made by the District Court and the Circuit Court of Appeals unless clear error is shown, should not be strictly applied in a case brought here by certiorari to settle a conflict between decisions of two circuit courts of appeals concerning the validity of a patent for an invention. *Id.*
3. Patent No. 1,046,066 issued December 3, 1912, to Thomson Electric Welding Company, assignee of Harmatta, for improvements in electric welding, viz., for the process known as "spot welding", whereby sheets or plates of metal are welded together in spots, in lieu of riveting,—is void for want of patentable invention. P. 448.

281 Fed. 680, affirmed.

CERTIORARI to a decree of the Circuit Court of Appeals affirming a decree of the District Court which held void a patent and dismissed a bill for infringement.
